Matrix group recognition in GAP

Max Neunhöffer

University of St Andrews

15.9.2007

Matrix groups ...

Let \mathbb{F}_q be the field with q elements and

$$\mathrm{GL}_n(\mathbb{F}_q) := \{M \in \mathbb{F}_q^{n \times n} \mid M \text{ invertible}\}$$

Given: $M_1, \dots, M_k \in \mathrm{GL}_n(\mathbb{F}_q)$

Then the M_i generate a group $G \leq \mathrm{GL}_n(\mathbb{F}_q)$.

It is **finite**, we have $|\mathrm{GL}_n(\mathbb{F}_q)| = q^{n(n-1)/2} \prod_{i=1}^n (q^i - 1)$

What do we want to determine about G ?

- The group order $|G|$
- Membership test: Is $M \in \mathrm{GL}_n(\mathbb{F}_q)$ in G ?
- Homomorphisms $\varphi : G \rightarrow H$?
- Kernels of homomorphisms? Is G simple?
- Comparison with known groups
- (Maximal) subgroups?
- ...

Verification

Status of our
implementation

Let $n \in \mathbb{N}$ and S_n be the **symmetric group**:

$$S_n = \{\pi : \{1, \dots, n\} \rightarrow \{1, \dots, n\} \mid \pi \text{ bijective}\}.$$

Given: $\pi_1, \dots, \pi_k \in S_n$

Then the π_i generate a group $G \leq S_n$.

It is **finite**, we have $|S_n| = n!$

Let \mathbb{F}_q be the field with q elements and

$$\text{GL}_n(\mathbb{F}_q) := \{M \in \mathbb{F}_q^{n \times n} \mid M \text{ invertible}\}$$

Given: $M_1, \dots, M_k \in \text{GL}_n(\mathbb{F}_q)$

Then the M_i generate a group $G \leq \text{GL}_n(\mathbb{F}_q)$.

It is **finite**, we have $|\text{GL}_n(\mathbb{F}_q)| = q^{n(n-1)/2} \prod_{i=1}^n (q^i - 1)$

Permutation groups

Let $n \in \mathbb{N}$ and S_n be the **symmetric group**:

$$S_n = \{\pi : \{1, \dots, n\} \rightarrow \{1, \dots, n\} \mid \pi \text{ bijective}\}.$$

Given: $\pi_1, \dots, \pi_k \in S_n$

Then the π_i generate a group $G \leq S_n$.

It is **finite**, we have $|S_n| = n!$.

We can determine about G algorithmically (e.g.):

- The group order $|G|$
- Membership test: Is $M \in S_n$ in G ?
- Homomorphisms $\varphi : G \rightarrow H$?
- Kernels of homomorphisms? Is G simple?
- Comparison with known groups
- (Maximal) subgroups?
- ...

In standard GAP:

```
gap> ugens;  
[ <an immutable 56x56 matrix over GF2>,  
  <an immutable 56x56 matrix over GF2> ]  
gap> u := Group(ugens);;  
gap> Size(u); time;  
252000  
341277  
gap> Image(NiceMonomorphism(u));  
<permutation group with 2 generators>
```

Using the upcoming **genss** package (with F. Noeske):

```
gap> Size(StabilizerChain(u)); time;  
252000  
1368
```

For “bigger” matrix groups both approaches **do not work**.

Problem

Let \mathbb{F}_q be the field with q elements and

$$M_1, \dots, M_k \in \text{GL}_n(\mathbb{F}_q).$$

Find for $G := \langle M_1, \dots, M_k \rangle$:

- The group order $|G|$ and
- an algorithm that, given $M \in \text{GL}_n(\mathbb{F}_q)$,
 - **decides**, whether or not $M \in G$ and
 - if so, expresses M **as word in the M_i** .

If this problem is solved, we call

$\langle M_1, \dots, M_k \rangle$ recognised constructively.

Complexity of algorithms

Verification

Status of our
implementation

To measure the **efficiency** of an algorithm, we consider a class \mathcal{P} of problems, that the algorithm can solve.

We assign to each $P \in \mathcal{P}$ its size $g(P)$,

and prove an upper bound for the runtime $L(P)$ of the algorithm for P :

$$L(P) \leq f(g(P))$$

for some function f .

The **growth rate of f** measures the **complexity**.

Example (Constructive matrix group recognition)

- Problem given by $M_1, \dots, M_k \in \text{GL}_n(\mathbb{F}_q)$.
- Size determined by n , k and $\log q$.
- Runtime should be \leq a **polynomial** in n , k and $\log q$.

Definition (Monte Carlo algorithms)

A Monte Carlo algorithm with error probability ϵ is an algorithm, that is **guaranteed** to terminate after a finite time, such that the **probability** that it returns a **wrong result** is at most ϵ .

Definition (Las Vegas algorithm)

A Las Vegas algorithm with error probability ϵ is an algorithm, that is **guaranteed** to terminate after a finite time, such that the **probability** that it **fails** is at most ϵ .

Example: Comp. of $|G| = 4\,089\,470\,473\,293\,004\,800$ for permutation group $G = \langle \pi_1, \pi_2 \rangle$ ($n = 137\,632$):

deterministic alg.: 112s **Monte Carlo $\epsilon = 1\%$:** 6s

Saving: 95% of runtime

Problem

Let \mathbb{F}_q be the field with q elements and

$$M_1, \dots, M_k \in \text{GL}_n(\mathbb{F}_q).$$

Find for $G := \langle M_1, \dots, M_k \rangle$:

- The group order $|G|$ and
- an algorithm that, given $M \in \text{GL}_n(\mathbb{F}_q)$,
 - **decides**, whether or not $M \in G$, and,
 - if so, expresses M **as word in the M_i** .
- The **runtime** should be bounded from above by a **polynomial in n , k and $\log q$** .
- A Monte Carlo Algorithmus is enough. **(Verification!)**

If this problem is solved, we call

$\langle M_1, \dots, M_k \rangle$ **recognised constructively.**

Troubles

The discrete logarithm problem

If $M_1 = [z] \in \mathbb{F}_q^{1 \times 1}$ with z a primitive root of \mathbb{F}_q . Then:

Given $0 \neq [x] \in \mathbb{F}_q^{1 \times 1}$, find $i \in \mathbb{N}$ such that $[x] = [z]^i$.

There is no solution in polynomial time in $\log q$ known!

Integer factorisation

Some methods need a factorisation of $q^i - 1$ for an $i \leq n$.

There is no solution in polynomial time in $\log q$ known!

In practice q is small \Rightarrow no problem.

We ignore both!

What is a reduction?

Let $G := \langle M_1, \dots, M_k \rangle \leq \text{GL}_n(\mathbb{F}_q)$.

A **reduction** is a group homomorphism

$$\begin{aligned} \varphi : G &\rightarrow H \\ M_i &\mapsto P_i \quad \text{for all } i \end{aligned}$$

with the following properties:

- $\varphi(M)$ is **explicitly computable** for all $M \in G$
- φ is **surjective**: $H = \langle P_1, \dots, P_k \rangle$
- H is in some sense “**smaller**”
- or at least “**easier to recognise constructively**”
- e.g. $H \leq S_m$ or $H \leq \text{GL}_{n'}(\mathbb{F}_{q'})$ with $n' \log q' < n \log q$

Computing the kernel

Let $\varphi : G \rightarrow H$ be a reduction and assume that H is already recognised constructively.

Then we can compute the kernel N of φ :

- 1 Generate a (pseudo-) random element $M \in G$,
- 2 map it with φ onto $\varphi(M) \in H = \langle P_1, \dots, P_k \rangle$,
- 3 express $\varphi(M)$ as word in the P_i ,
- 4 evaluate the same word in the M_i ,
- 5 get element $M' \in G$ with $M \cdot M'^{-1} \in N$.
- 6 If M is uniformly distributed in G
then $M \cdot M'^{-1}$ is uniformly distributed in N
- 7 Repeat.

→ Monte Carlo algorithm to compute N

Recognising image and kernel suffices

Let $\varphi : G \rightarrow H$ be a reduction and assume that **both** H **and** the kernel $N = \langle N_1, \dots, N_m \rangle$ of φ are already recognised constructively.

Then we have recognised G constructively:

$$|G| = |H| \cdot |N|. \text{ And for } M \in \text{GL}_n(\mathbb{F}_q):$$

- 1 map M with φ onto $\varphi(M) \in H = \langle P_1, \dots, P_k \rangle$,
- 2 express $\varphi(M)$ as word in the P_i ,
- 3 evaluate the same word in the M_i ,
- 4 get element $M' \in G$ such that $M \cdot M'^{-1} \in N$,
- 5 express $M \cdot M'^{-1}$ as word in the N_j ,
- 6 get M as word in the M_i and N_j :

$$M' = \prod \text{ in the } M_i, \quad M \cdot M'^{-1} = \prod \text{ in the } N_j$$

$$\Rightarrow M = (\prod \text{ in the } N_j) \cdot (\prod \text{ in the } M_i).$$
- 7 If $M \notin G$, then **at least** one step does not work.

Recursion: composition trees

We get a tree:

Up arrows: inclusions

Down arrows: homomorphisms

Old idea, substantial improvements: Seress & N. 2006

Example: invariant subspace

Max Neunhöffer

Let $V = \mathbb{F}_q^n$, then G acts on V .Let $W \leq V$ be an **invariant subspace**, i.e.:

$$MW = W \quad \text{for all } M \in G$$

Choose basis (w_1, \dots, w_d) of W and extend to a basis

$$(w_1, \dots, w_d, w_{d+1}, \dots, w_n)$$

of V . After a **base change** the matrices in G look like this:

$$\left[\begin{array}{c|c} A & B \\ \hline \mathbf{0} & D \end{array} \right] \quad \text{with } A \in \mathbb{F}_q^{d \times d}, B \in \mathbb{F}_q^{d \times (n-d)}, D \in \mathbb{F}_q^{(n-d) \times (n-d)}$$

and

$$G \rightarrow \text{GL}_{n-d}(\mathbb{F}_q), \left[\begin{array}{c|c} A & B \\ \hline \mathbf{0} & D \end{array} \right] \mapsto D$$

is a homomorphism of groups.

Troubles

Reduction

Homomorphisms
Computing the kernel
Recursion: composition
trees
Example: invariant
subspace
Finding reductions

Solution for leaves

Classifications
Recognition of the groups
Standard generators

Verification

Status of our
implementation

Example: invariant subspace

$$G \rightarrow \mathrm{GL}_{n-d}(\mathbb{F}_q), \begin{bmatrix} A & B \\ \mathbf{0} & D \end{bmatrix} \mapsto D$$

is a homomorphism of groups, its kernel is

$$N := \left\{ \begin{bmatrix} A & B \\ \mathbf{0} & D \end{bmatrix} \in G \mid D = \mathbf{1} \right\}.$$

The mapping

$$N \rightarrow \mathrm{GL}_d(\mathbb{F}_q), \begin{bmatrix} A & B \\ \mathbf{0} & \mathbf{1} \end{bmatrix} \mapsto A$$

also is a homomorphism of groups and has kernel

$$N_2 := \left\{ \begin{bmatrix} A & B \\ \mathbf{0} & D \end{bmatrix} \in G \mid A = D = \mathbf{1} \right\}.$$

This group is a p -group for $q = p^e$:

$$\begin{bmatrix} \mathbf{1} & B \\ \mathbf{0} & \mathbf{1} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{1} & B' \\ \mathbf{0} & \mathbf{1} \end{bmatrix} = \begin{bmatrix} \mathbf{1} & B + B' \\ \mathbf{0} & \mathbf{1} \end{bmatrix}$$

Together with a reduction additional information is gained!

How to find reductions?

Aschbacher has defined classes C1 to C8 of subgroups of $GL_n(\mathbb{F}_q)$.

Theorem (Aschbacher, 1984)

Let $G \leq GL_n(\mathbb{F}_q)$ and $Z := G \cap Z(GL_n(\mathbb{F}_q))$ the subgroup of scalar matrices. Then G lies in *at least one* of the classes C1 to C8 *or* we have:

- $T \subseteq G/Z \subseteq \text{Aut}(T)$
for a non-abelian simple group T , *and*
- G acts absolutely irreducibly on $V = \mathbb{F}_q^n$.

(This last case is called C9.)

Thus we can call in *heavy artillery*:

- the *classification of finite simple groups*
- the *modular representation theory of simple groups*

Approach for leaves of the tree

If none of the algorithms for C1 to C8 has succeeded:

- 1 For “**small**” groups compute **direct isomorphism** onto a permutation group.
- 2 **Determine**, for which (simple) group $T \leq G/Z \leq \text{Aut}(T)$ holds.
- 3 **Find** an explicit isomorphism onto a “standard copy” of an intermediate group S .
- 4 Finally **use** information about S to **recognise** G **constructively**.

This uses:

- the classification of **finite simple groups**
- information about their **automorphism groups**
- information about **element orders**
- information about **conjugacy classes**
- classifications of the **irreducible representations**
- information about the **subgroup structure**

Methods for non-constructive recognition:

- Knowledge about representations narrows down the possibilities
- Statistics about orders of random elements

Usually this leads to **Monte Carlo algorithms**.

Standard generators

Max Neunhoffer

In G we can only multiply, invert and compute orders.
 Suppose: $G \cong S$ with $T \leq S \leq \text{Aut}(T)$ and T simple.

Verification

Status of our
implementation

Find a tuple $(s_1, \dots, s_r) \in S^r$ together with certain words p_1, \dots, p_m in the s_i , such that:

- $S = \langle s_1, \dots, s_r \rangle$,
- if $(s'_1, \dots, s'_r) \in S^r$ with
 - $|s_i| = |s'_i|$ for $1 \leq i \leq r$,
 - $|p_j| = |p'_j|$ for $1 \leq j \leq m$
 (the p'_j are the same words in the s'_i),

then $s_i \mapsto s'_i$ for $1 \leq i \leq r$ defines an automorphism of S .

Such elements are called “standard generators” of S .

We find $G \cong S$ explicitly by finding a tuple (M_1, \dots, M_r) of standard generators in G .

Often this leads to efficient Las Vegas algorithms to find explicit isomorphisms.

Everywhere we used randomised methods:
Las Vegas and **Monte Carlo**.

⇒ **We have to check whether our result is correct!**

Idea:

- Find **(short) presentations** for the leaf-groups,
- put these together to one for the whole group.
- Check the **relations** and thus prove the result.

Status of our implementation

We have

- a package **recogbase** providing a **framework** to implement **recognition algorithms** and **composition trees** (Ákos Seress, N.),
- a package **recog** collecting **methods** to find **reductions** and **recognise leafs constructively**,
Authors (currently): P. Brooksbank, M. Law, S. Linton, N., A. Niemeyer, E. O'Brien, Á. Seress,
- complete **asymptotically best methods** to handle permutation groups,
- methods for most **Aschbacher classes** for matrix groups and projective groups (**some improved algorithms still needed**),
- nearly ready **non-constructive recognition**,
- a few **leaf methods**,
- **no verification**.
