Burnside rings and arithmetical properties of finite simple groups

Wolfgang Kimmerle

IGT, University of Stuttgart

Arithmetic of group rings and related structures, 22.-26. März 2010

Notations

| | |
|---------------|----------------------------------------------------------------|
| G | finite group |
| $\Omega(G)$ | Burnside ring of G |
| $M(G)$ | table of marks of G |
| $\pi_e(G)$ | the set of element orders of G called the spectrum of G |
| $\mathbb{C}G$ | complex group algebra of G |

Throughout we use freely the classification of the finite simple groups.

Back to spectra

A mathematical object based on algebraic numbers and associated to a finite group G is called an **arithmetic property of G** .

It is a natural and old question of group theory to ask which properties of G are reflected by such an arithmetical property.

On the other hand, it is a fundamental question of representation theory to ask which properties of a group G are determined by its representations.

Questions

A typical question is which properties of a finite group are reflected by its Burnside ring $\Omega(G)$? This talk deals with the following two special cases.

- **Question 1.** Is a finite simple group G determined up to isomorphism by its Burnside ring $\Omega(G)$?

Questions

A typical question is which properties of a finite group are reflected by its Burnside ring $\Omega(G)$? This talk deals with the following two special cases.

- **Question 1.** Is a finite simple group G determined up to isomorphism by its Burnside ring $\Omega(G)$?
- **Question 2.** More generally, are the composition factors of a finite group G determined by $\Omega(G)$?

Block description of Burnside rings

$$\Omega(G) = \Omega(G)^s \times \Omega(N_G(P_2)/P_2)^s \times \dots \times \Omega(N_G(P_k)/P_k)^s$$

where P_1, P_2, \dots, P_k are the representatives of the conjugacy classes of perfect subgroups of G with $P_1 = 1$.

Let X be a finite group. Then $\Omega(X)^s$ denotes the ideal generated by all X/H with H soluble.

$\Omega(X)^s$ is called the principal block of the Burnside ring $\Omega(X)$.

(Conjecture Wujie Shi 1987, Kourovka Notebook 12.39)

Let G be a finite group and let S be a finite simple group. Assume that $\pi_e(S) = \pi_e(G)$ and that $|S| = |G|$. Then $G \cong S$.

State of the art 2007

Let S be a finite simple group. Then Shi's Conjecture holds provided S is one of the following groups:

- (i) G is of prime order.
- (ii) G is an alternating group of degree ≥ 5 .
- (iii) G is a sporadic simple group.

Xianhua Li, Thesis Potsdam 2008

Let G and H be finite groups. Assume that G is simple and that G and H have the same Sylow numbers and the same order. Then

$$G \cong H \text{ or } \{G, H\} = \{B_n(q), C_n(q)\}$$

Now $\Omega(G) \cong \Omega(H) \implies |G| = |H|$ and that the Sylow numbers coincide. Using Xianhua Li's result it remains to consider the case $B_n(q)$ versus $C_n(q)$. This is settled via centralizers of involutions.

Because

$$\Omega(G) \cong \Omega(H) \implies |N_G(U)| = |N_H(U_*)|$$

for each soluble element U of $V(G)$, it follows that the class lengths of involutions of H and G coincide. In particular the number of involutions of H and G coincides.

Now $\Omega(G) \cong \Omega(H) \implies |G| = |H|$ and that the Sylow numbers coincide. Using Xianhua Li's result it remains to consider the case $B_n(q)$ versus $C_n(q)$. This is settled via centralizers of involutions.

Because

$$\Omega(G) \cong \Omega(H) \implies |N_G(U)| = |N_H(U_*)|$$

for each soluble element U of $V(G)$, it follows that the class lengths of involutions of H and G coincide. In particular the number of involutions of H and G coincides.

But $B_n(q)$ and $C_n(q)$ have different numbers of involutions.

This completes the second approach to the theorem establishing a complete proof.

A main tool for the proof of the conjecture of Wujie Shi for many simple groups is the Gruenberg - Kegel graph $\Gamma(G)$ of a finite group (also called the prime graph of G).

This is the graph whose vertices are the primes p dividing $|G|$. Two different vertices p and q are joined by an edge provided there is a group element of order pq .

Groups with isomorphic Burnside rings have the same Gruenberg - Kegel graph.

Groups with isomorphic Burnside rings have the same Gruenberg - Kegel graph.

K. W. Gruenberg and O. Kegel have shown that groups with disconnected prime graph have a very restricted structure. Using the classification of the finite simple groups, J. S. Williams proved that G has a nilpotent π -Hall subgroup provided the primes of π form a connecting component of $\Gamma(G)$ consisting of odd primes.

Groups with isomorphic Burnside rings have the same Gruenberg - Kegel graph.

K. W. Gruenberg and O. Kegel have shown that groups with disconnected prime graph have a very restricted structure. Using the classification of the finite simple groups, J. S. Williams proved that G has a nilpotent π -Hall subgroup provided the primes of π form a connecting component of $\Gamma(G)$ consisting of odd primes.

Because groups with isomorphic Burnside rings have isomorphic sublattice of nilpotent groups this provides in contrast to the use of solely the spectrum an easier and more direct way for such groups to decide whether they are determined by their Burnside ring.

Note. A finite group has at most 6 prime graph components. A finite soluble group has at most 2 prime graph components.

C.Höfert, Thesis Stuttgart 2008

Let G and H be finite groups. Assume that the Gruenberg-Kegel graph $\Gamma(G)$ has at least three components. Then $\Omega(G) \cong \Omega(H)$ implies that G and H have the same composition factors.
