# Orthogonal representations of $\mathrm{SL}_{2}(q)$ in defining characteristic 

Tobias Braun*and Gabriele Nebe ${ }^{\dagger \ddagger}$

#### Abstract

This paper determines the type of the invariant quadratic form for all irreducible modules of the groups $\mathrm{SL}_{2}(q)$ in defining characteristic.

## 1 Introduction

Let $\rho: G \rightarrow \mathrm{GL}_{n}(K)$ be an absolutely irreducible representation of a finite group $G$. Then $\rho$ is called orthogonal, if $\rho(G)$ fixes a non-degenerate quadratic form $Q$; in this case $\rho(G)$ is a subgroup of the orthogonal group of $Q$. If $K$ is a finite field and $n$ is even, there are two isomorphism classes of orthogonal groups, $O^{+}$and $O^{-}$. As field extensions are well controlled (see [6, Proposition 4.9]) it is enough to consider the minimal possible field $K$, the field of definition, that is generated by the traces of the matrices in $\rho(G)$.

In a long term project with Richard Parker and Thomas Breuer we aim to determine the type ( + or - ) of all orthogonal absolutely irreducible representations of the small finite simple groups $G$.

For all prime powers $q=p^{f}$ the paper [1] provides the relevant information for the orthogonal representations of $\mathrm{SL}_{2}(q)$ over fields $K$ of characteristic 0 . This immediately yields the type for all characteristics not dividing the group order. Using the methods of [5] and the decomposition matrices available in [2] one can also deduce the orthogonal type in non-defining characteristic. The present paper deals with the remaining case, where $\operatorname{char}(K)=p=\operatorname{char}\left(\mathbb{F}_{q}\right)$, the so-called defining characteristic. The main result is given in Theorem 3.7. Its proof is based on the observation that the restriction of all relevant representations to the cyclic subgroup $T \leq \mathrm{SL}_{2}(q)$ of order $|T|=q+1$ (a non-split torus) is an orthogonal direct sum of irreducible unitary representations.

## 2 Quadratic forms over finite fields

### 2.1 Quadratic forms

Let $K$ be a field and $V$ a finite dimensional vector space over $K$. A quadratic form $Q$ is a map $Q: V \rightarrow K$ such that $Q(a x)=a^{2} Q(x)$ for all $a \in K, x \in V$ and such that the polarisation

$$
B_{Q}: V \times V \rightarrow K, B_{Q}(x, y):=Q(x+y)-Q(x)-Q(y)
$$

is a bilinear form. The quadratic form $Q$ is called non-degenerate if the radical of $B_{Q}$ is $\{0\}$. Note that the polarisation of a quadratic form is always a symmetric bilinear form. Also $2 Q(x)=B_{Q}(x, x)$, so over a field of characteristic $\neq 2$ quadratic forms and symmetric bilinear forms are equivalent notions. If $\operatorname{char}(K)=2$ then $B_{Q}(x, x)=0$ for all $x$, so $B_{Q}$ is alternating, and, in particular, the dimension of a non-degenerate quadratic form is even.

### 2.2 Quadratic forms over finite fields

Let $\mathbb{F}_{q}$ denote the field with $q$ elements. Then it is well known that every non-degenerate quadratic form $Q$ of dimension $\geq 3$ contains isotropic vectors, i.e. vectors $v \neq 0$ with $Q(v)=0$. We may conclude that such forms split off a hyperbolic plane

$$
\mathbb{H}\left(\mathbb{F}_{q}\right):=(\langle v, w\rangle, Q) \text { with } Q(a v+b w)=a b
$$

as an orthogonal summand. There is a unique anisotropic form of dimension $2, N\left(\mathbb{F}_{q}\right)$. Here the underlying space is $\mathbb{F}_{q^{2}}$ and the quadratic form is the norm form $Q(x):=x x^{q}$ for all $x \in \mathbb{F}_{q^{2}}$.

Hence on a vector space $V=\mathbb{F}_{q}^{2 m}$ of even dimension there are two non-isometric quadratic forms

$$
\begin{equation*}
Q_{2 m}^{+}(q):=\mathbb{H}\left(\mathbb{F}_{q}\right)^{m} \text { and } Q_{2 m}^{-}(q):=\mathbb{H}\left(\mathbb{F}_{q}\right)^{m-1} \perp N\left(\mathbb{F}_{q}\right), \tag{1}
\end{equation*}
$$

which we call of + type and of - type respectively.
Remark 2.1. The orthogonal sums of these forms behave as expected:

$$
Q_{2 m}^{+}(q) \perp Q_{2 n}^{+}(q)=Q_{2 m}^{-}(q) \perp Q_{2 n}^{-}(q)=Q_{2(m+n)}^{+}(q), Q_{2 m}^{-}(q) \perp Q_{2 n}^{+}(q)=Q_{2(m+n)}^{-}(q)
$$

Fact 2.2. (see for instance [4, Kapitel IV])

- The Witt index, i.e. the dimension of a maximal isotropic subspace, of $Q_{2 m}^{+}(q)$ is $m$ and $Q_{2 m}^{-}(q)$ has Witt index $m-1$.
- The number of non-zero isotropic vectors in $Q_{2 m}^{+}(q)$ is $\left(q^{m}-1\right)\left(q^{m-1}+1\right)$ and in $Q_{2 m}^{-}(q)$ one gets $\left(q^{m}+1\right)\left(q^{m-1}-1\right)$.

Proposition 2.3. For any non-zero $\alpha \in \mathbb{F}_{q^{m}}$ the quadratic form

$$
Q_{\alpha}: \mathbb{F}_{q^{2 m}} \rightarrow \mathbb{F}_{q}, Q_{\alpha}(x):=\operatorname{trace}_{\mathbb{F}_{q^{m}} / \mathbb{F}_{q}}\left(\alpha x^{q^{m}+1}\right)
$$

is isometric to $Q_{2 m}^{-}(q)$.
Proof. We check that for $x, y \in \mathbb{F}_{q^{2 m}}$

$$
Q_{\alpha}(x+y)-Q_{\alpha}(x)-Q_{\alpha}(y)=\operatorname{trace}_{\mathbb{F}_{q^{m}} / \mathbb{F}_{q}}\left(x^{q^{m}} \alpha y+y^{q^{m}} \alpha x\right)=\operatorname{trace}_{\mathbb{F}_{q^{2}} / \mathbb{F}_{q}}\left(x^{q^{m}} \alpha y\right)
$$

by the transitivity of the trace. So the polarisation of $Q_{\alpha}$ is given by

$$
B_{\alpha}(x, y)=\operatorname{trace}_{\mathbb{F}_{q^{2 m}} / \mathbb{F}_{q}}\left(x^{q^{m}} \alpha y\right) \text { for all } x, y \in \mathbb{F}_{q^{2 m}}
$$

As the trace form of separable extensions is a non-degenerate bilinear form and the Galois automorphism $x \mapsto x^{q^{m}}$ of $\mathbb{F}_{q^{2 m}}$ is bijective, also $B_{\alpha}$ is non-degenerate.
One way to see that $Q_{\alpha}$ is isometric to $Q_{2 m}^{-}(q)$ is to count the number of isotropic vectors: The norm $N: \mathbb{F}_{q^{2 m}} \rightarrow \mathbb{F}_{q^{m}}, x \mapsto x^{q^{m}} x$ is a surjective anisotropic quadratic form that restricts to a group epimorphism on the multiplicative groups. So for any $a \in \mathbb{F}_{q^{m}} \backslash\{0\}$ the number of $x \in \mathbb{F}_{q^{2 m}} \backslash\{0\}$ with $N(x)=a$ is $q^{m}+1$. The quadratic form $Q_{\alpha}$ is the composition of $N$ with multiplication by $\alpha$ followed by the trace. The trace is an $\mathbb{F}_{q^{-}}$ linear surjective map form $\mathbb{F}_{q^{m}}$ to $\mathbb{F}_{q}$, so the kernel of the trace is an $(m-1)$-dimensional subspace of $\mathbb{F}_{q^{m}}$ and, in particular, contains $q^{m-1}-1$ non-zero elements. So the number of isotropic vectors of $Q_{\alpha}$ is $\left(q^{m-1}-1\right)\left(q^{m}+1\right)$.
Proposition 2.4. Let $Q: V \rightarrow \mathbb{F}_{q}$ be a non-degenerate quadratic form and $G \leq O(Q)$ an abelian subgroup of the orthogonal group of $Q$ such that
(a) The $\mathbb{F}_{q}$-algebra $A$ spanned by the matrices in $G$ is semi-simple, with

$$
A=\bigoplus_{i=1}^{n} K_{i} \text { for extension fields } K_{i} \text { of } \mathbb{F}_{q}
$$

(b) All simple summands $K_{i}$ are invariant under the adjoint involution of $B_{Q}$.
(c) The restriction of this involution to $K_{i}$ is non-trivial for all i.

Then $Q$ is of + type if and only if the number of composition factors of the $A$-module $V$ is even.

Proof. The set of isomorphism classes of simple $A$-modules is $\left\{K_{i} \mid 1 \leq i \leq n\right\}$ and the $A$-module $V$ is hence the direct sum $V \cong \bigoplus_{i=1}^{n} K_{i}^{d_{i}}$ for some $d_{i} \in \mathbb{N}$. As the adjoint involution fixes each primitive idempotent of $A$, the summands $K_{i}^{d_{i}}$ are pairwise orthogonal. The restriction of the involution to the simple summand $K_{i}$ of $A$ is the field automorphism $F_{i}$ of order 2, so the bilinear form $B_{Q}$ induces Hermitian forms on these orthogonal summands. So there are $\alpha_{i 1}, \ldots, \alpha_{i d_{i}}$ in the fixed field of $F_{i}$ such that

$$
Q=\perp_{i=1}^{n} \perp_{j=1}^{d_{i}} Q_{\alpha_{i j}}
$$

for quadratic forms $Q_{\alpha_{i j}}: K_{i} \rightarrow \mathbb{F}_{q}$ as in Proposition 2.3. As these are of - type, the statement follows by applying the addition formulas from Remark 2.1.

Note that the assumption from Proposition 2.4 is equivalent to the assumption that the restriction of $V$ to $G$ is an orthogonally stable orthogonal representation in the sense of [5, Definition 5.12]. In the language of [5] the statement of Proposition 2.4 can also be deduced from [5, Proposition 3.12].

## 3 The orthogonal representations of $\mathrm{SL}_{2}\left(p^{f}\right)$

In this section we fix the following notation:

- $p$ is a prime, $q:=p^{f}$,

$$
G:=\mathrm{SL}_{2}(q):=\left\{\left.\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \in \mathbb{F}_{q}^{2 \times 2} \right\rvert\, a d-b c=1\right\}
$$

is the group of determinant 1 matrices over the finite field with $q$ elements.

- $V:=\mathbb{F}_{q}^{2}$ is the natural $\mathbb{F}_{q} G$-module.
- If $q$ is odd then $Z\left(\mathrm{SL}_{2}(q)\right)=\left\langle-I_{2}\right\rangle$ and $\operatorname{PSL}_{2}(q)=\mathrm{SL}_{2}(q) / Z\left(\mathrm{SL}_{2}(q)\right)$ is simple for $q \geq 5$.
- If $q$ is even, then $\mathrm{SL}_{2}(q)$ is simple for $q \geq 4$.
- The group $\mathrm{SL}_{2}(2)$ is isomorphic to $S_{3}$.

### 3.1 The irreducible modules and their fields of definition

For $f=1$, the following is well known:
Fact 3.1. The irreducible $\mathbb{F}_{p} \mathrm{SL}_{2}(p)$-modules are given by $W_{0}, \ldots, W_{p-1}$, where

$$
W_{k}:=\operatorname{Sym}_{k}(V)=\mathbb{F}_{p}[x, y]_{d e g=k}
$$

is the space of homogeneous polynomials on $V$ of degree $k$. All $W_{k}$ are absolutely irreducible and the dimension of $W_{k}$ is $k+1$.

For arbitrary $f \in \mathbb{N}$ we know that $\mathbb{F}_{q}$ is a splitting field for $\mathrm{SL}_{2}(q)$ and the irreducible $\mathbb{F}_{q} \mathrm{SL}_{2}(q)$-modules are given by Steinberg's tensor product theorem: The Galois group $\operatorname{Gal}\left(\mathbb{F}_{p^{f}} / \mathbb{F}_{p}\right)=\langle F\rangle$ acts on the group $\mathrm{SL}_{2}(q)$ by applying the Galois automorphism to the entries of the matrices. For $0 \leq i \leq f-1$ let $V^{[i]}$ denote the natural $\mathbb{F}_{q} \mathrm{SL}_{2}(q)$-module $V$ where the action is twisted by $F^{i}$ and $W_{k}^{[i]}:=\operatorname{Sym}_{k}\left(V^{[i]}\right)$.
Fact 3.2. The irreducible $\mathbb{F}_{q} \mathrm{SL}_{2}(q)$-modules are given by

$$
W(\mathbf{k})=W\left(k_{0}, \ldots, k_{f-1}\right)=W_{k_{0}}^{[0]} \otimes \ldots \otimes W_{k_{f-1}}^{[f-1]}
$$

for $\mathbf{k}:=\left(k_{0}, \ldots, k_{f-1}\right) \in\{0, \ldots, p-1\}^{f}$. The $W(\mathbf{k})$ are pairwise non-isomorphic, absolutely irreducible and of dimension $\operatorname{dim}\left(W\left(k_{0}, \ldots, k_{f-1}\right)\right)=\prod_{i=0}^{f-1}\left(k_{i}+1\right)$.

The action of the Galois group on these irreducible modules is given by cyclic permutation:

$$
W\left(k_{0}, \ldots, k_{f-1}\right)^{F} \cong W\left(k_{f-1}, k_{0}, \ldots, k_{f-2}\right)
$$

As the modules $W(\mathbf{k})$ are pairwise non-isomorphic, the representation on $W(\mathbf{k})$ can be realised over the fixed field of $F^{\ell}$ if and only if

$$
\left(k_{0}, \ldots, k_{f-1}\right)=\left(k_{f-\ell}, k_{f-\ell+1}, \ldots, k_{f-\ell-1}\right)
$$

Remark 3.3. Let $\ell \geq 1$ be minimal such that

$$
\mathbf{k}:=\left(k_{0}, \ldots, k_{f-1}\right)=\left(k_{f-\ell}, k_{f-\ell+1}, \ldots, k_{f-\ell-1}\right)
$$

Then $\ell$ divides $f$. Put $\mathbb{F}(\mathbf{k}):=\mathbb{F}_{p^{\ell}}$ to be the fixed field of $F^{\ell}$ in $\mathbb{F}_{q}$. Then $\mathbb{F}(\mathbf{k})$ is the field of definition of the module $W(\mathbf{k})$.
By abuse of notation we denote the corresponding $\mathbb{F}(\mathbf{k}) \mathrm{SL}_{2}(q)$-module again by $W(\mathbf{k})$.

### 3.2 Invariant quadratic forms

For $A=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \mathbb{F}_{p^{f}}^{2 \times 2}$ and $J:=\left(\begin{array}{cc}0 & 1 \\ -1 & 0\end{array}\right)$ we have $A J A^{t r}=\operatorname{det}(A) J$, so the natural $\mathbb{F}_{q} \mathrm{SL}_{2}(q)$-module $V=\mathbb{F}_{q}^{2}$ carries a non-degenerate alternating $G$-invariant bilinear form. This yields a non-degenerate $G$-invariant bilinear form $B_{k}$ on the space of homogenous polynomials

$$
B_{k}: \mathbb{F}_{q}[x, y]_{d e g=k} \times \mathbb{F}_{q}[x, y]_{d e g=k} \rightarrow \mathbb{F}_{q}: B_{k}(g, h):=g\left(-\frac{\partial}{\partial y}, \frac{\partial}{\partial x}\right)(h(x, y)) .
$$

The form $B_{k}$ is symmetric if $k$ is even and alternating if $k$ is odd.
Remark 3.4. There is a special case for $q=2$. Here $V$ carries a non-degenerate quadratic form of - type and $\mathrm{SL}_{2}(2) \leq O_{2}^{-}(2)$.
Remark 3.5. (see [6, Proposition 3.4], [3, Proposition 9.1.2]) Let $G$ be a group and let $(V, B)$ and $\left(W, B^{\prime}\right)$ be $G$-invariant alternating non-degenerate bilinear forms on the $K G$-modules $V$ and $W$. Then

$$
Q: V \otimes W \rightarrow K, Q\left(\sum_{i=1}^{n} v_{i} \otimes w_{i}\right):=\sum_{i<j} B\left(v_{i}, v_{j}\right) B^{\prime}\left(w_{i}, w_{j}\right)
$$

is a $G$-invariant quadratic form on $V \otimes W$ with polarisation $B \otimes B^{\prime}$. If $U \leq V$ is an isotropic subspace, i.e. $B(U, U)=\{0\}$, then $Q(U \otimes W)=\{0\}$. In particular, the Witt index of $Q$ is $m:=\operatorname{dim}(V \otimes W) / 2$. If $K=\mathbb{F}_{q}$ is a finite field, this shows that $Q$ is isometric to $Q_{2 m}^{+}(q)$.

Proposition 3.6. Assume that $q \neq 2$. Let $\mathbf{k}:=\left(k_{0}, \ldots, k_{f-1}\right)$ and $\mathbb{F}(\mathbf{k})$ be as in Remark 3.3 and put $e(\mathbf{k}):=\mid\left\{i \mid k_{i}\right.$ is odd $\} \mid$. Then the $\mathbb{F}(\mathbf{k}) G$-module $W(\mathbf{k})$ carries a nondegenerate $G$-invariant quadratic form $Q_{\mathbf{k}}$ if and only if either
(i) $q$ is odd and $e(\mathbf{k})$ is even.
(ii) $q$ is even and $\operatorname{dim}(W(\mathbf{k})) \geq 4$.

If $\left[\mathbb{F}_{q}: \mathbb{F}(\mathbf{k})\right]$ is odd, then $Q_{\mathbf{k}}$ has maximal Witt index and hence is of + type.
Proof. (i) As $W(\mathbf{k})$ is absolutely irreducible any $G$-invariant bilinear form is a scalar multiple of $B_{\mathbf{k}}:=B_{k_{0}} \otimes \ldots \otimes B_{k_{f-1}}$. This form is symmetric if and only if $e(\mathbf{k})$ is even. (ii) If $q$ is even and $W(\mathbf{k})$ is a proper tensor product, then Remark 3.5 yields such an invariant quadratic form $Q_{\mathbf{k}}$. Since both orthogonal groups of dimension 2 are solvable, there cannot be an invariant quadratic form on $W(\mathbf{k})$ if $\operatorname{dim}(W(\mathbf{k}))=2$ and $q>2$.
In both cases ( $q$ even or odd) Remark 3.5 states that $Q_{\mathbf{k}}$ is of maximal Witt index over the splitting field $\mathbb{F}_{q}$. As odd degree extensions do not change the type of a quadratic form (see for instance [6, Proposition 4.9]) they are of the same type, if $\left[\mathbb{F}_{q}: \mathbb{F}(\mathbf{k})\right]$ is odd.

### 3.3 The type of $Q_{k}$

This section finishes the proof of our main result:
Theorem 3.7. Let $q \neq 2$. The quadratic form $Q_{\mathbf{k}}: W(\mathbf{k}) \rightarrow \mathbb{F}(\mathbf{k})$ from Proposition 3.6 is of + type except for the case that $\operatorname{dim}(W(\mathbf{k})) \equiv 4(\bmod 8)$ and $\left[\mathbb{F}_{q}: \mathbb{F}(\mathbf{k})\right]=2$ where this form is of - type.

The case $q=2$ is given in Remark 3.4.
Proposition 3.6 proves Theorem 3.7 in the case that $\left[\mathbb{F}_{q}: \mathbb{F}(\mathbf{k})\right]$ is odd so it remains to consider the case where this degree is even, i.e. $f$ is even and

$$
\mathbf{k}=\left(k_{0}, \ldots, k_{f / 2-1}, k_{0}, \ldots, k_{f / 2-1}\right)
$$

where at least one of the $k_{i}$ is odd. In this case we show that the non-split torus $T$ of $\mathrm{SL}_{2}(q)$ acts on $W(\mathbf{k})$ such that the image $A$ of $\mathbb{F}(\mathbf{k}) T$ in $\operatorname{End}(W(\mathbf{k}))$ is a semi-simple subalgebra that is a direct sum of even degree extension fields of $\mathbb{F}(\mathbf{k})$. Then Proposition 2.4 allows us to conclude that the type of $Q_{\mathbf{k}}$ is - if and only if the number of composition factors of the $A$-module $W(\mathbf{k})$ is odd.

Let $t \in \mathrm{SL}_{2}(q)$ denote an element of order $q+1$. Let $\tau, \tau^{q} \in \mathbb{F}_{q^{2}}$ denote the two eigenvalues of $t$ on the natural $\mathrm{SL}_{2}(q)$ module $V=\mathbb{F}_{q}^{2}$.

Lemma 3.8. Let $\mathbf{k}=\left(k_{0}, \ldots, k_{f-1}\right) \in\{0, \ldots, p-1\}^{f}$ and put $s(\mathbf{k}):=\sum_{i=0}^{f-1} k_{i} p^{i}$. Then $s(\mathbf{k}) \leq p^{f}-1$.
The eigenvalues of $t$ on $W(\mathbf{k})$ are exactly the elements $\tau^{e}$ with

$$
e \in E(\mathbf{k}):=\left\{s(\mathbf{k})-2 \sum_{i=0}^{f-1} x_{i} p^{i} \mid x_{i} \in\left\{0, \ldots, k_{i}\right\}\right\} \subseteq\{-s(\mathbf{k}), \ldots, s(\mathbf{k})\}
$$

Proof. After extending the field to $\mathbb{F}_{q^{2}}$ we choose a basis of $V$ consisting of eigenvectors of $t$. Then the monomials in $W_{k}^{[i]}$ are eigenvectors of $t$ where the eigenvalue of $x^{k-j} y^{j}$ is $\tau^{e}$ with $e=(k-2 j) p^{i}$. So the eigenvalues of $t$ on $W(\mathbf{k})$ are the elements $\tau^{e}$ where

$$
e \in E(\mathbf{k}):=\left\{\sum_{i=0}^{f-1} m_{i} p^{i} \mid-k_{i} \leq m_{i} \leq k_{i}, k_{i}-m_{i} \text { even }\right\} .
$$

Replacing $m_{i}$ by $k_{i}-2 x_{i}$ yields the description in the lemma.
Lemma 3.9. We have $0 \in E(\mathbf{k})$ if and only if all $k_{i}$ are even.
If $p$ is odd, $f$ is even, and one of $\pm\left(p^{f}+1\right) / 2 \in E(\mathbf{k})$ then $s(\mathbf{k})$ is odd.
Proof. If $0 \in E(\mathbf{k})$ then there are $x_{i} \in\left\{0, \ldots, k_{i}\right\}$ such that $\sum_{i=0}^{f-1} k_{i} p^{i}=\sum_{i=0}^{f-1} 2 x_{i} p^{i}$. Taking the equation mod $p$, we get that $2 x_{0} \equiv_{p} k_{0}$. As $2 x_{0} \in\left\{0,2, \ldots, 2 k_{0}\right\}$ and $k_{0}<p$, we hence have $2 x_{0}=k_{0}$ so $k_{0}$ is even and $x_{0}=k_{0} / 2$. Continuing like this, we obtain that $x_{i}=k_{i} / 2$ for all $i$.
Now assume that $p$ is odd, $f$ is even, and $\pm\left(p^{f}+1\right) / 2 \in E(\mathbf{k})$. Then $s(\mathbf{k})=2 \sum_{i=0}^{f-1} x_{i} p^{i} \pm$ $\left(p^{f}+1\right) / 2$. As $f$ is even, $\left(p^{f}+1\right) / 2$ is odd and so is $s(\mathbf{k})$.
Proof. (of Theorem 3.7) Under the assumptions of the lemma $s(\mathbf{k})=\left(1+p^{f / 2}\right) \sum_{i=0}^{f / 2-1} k_{i} p^{i}$ is even and hence Lemma 3.9 shows that $t$ has no eigenvalues $\pm 1$ on $W(\mathbf{k})$. Now the order of $t$ is $p^{f}+1$. As $\operatorname{gcd}\left(p^{f}-1, p^{f}+1\right)=2$ (or 1 ) all eigenvalues of $t$ that are not $\pm 1$ generate a quadratic extension of $\mathbb{F}_{q}$. Let $A:=\mathbb{F}(\mathbf{k})[t] \leq \operatorname{End}(W(\mathbf{k}))$ be the $\mathbb{F}(\mathbf{k})$-subalgebra generated by the endomorphism $t$ of $W(\mathbf{k})$. Then $A=\bigoplus_{i=1}^{n} K_{i}$ is semi-simple and commutative. As the adjoint involution of $B_{Q}$ inverts the elements of $O(Q)$ and inverting the eigenvalues of $t$ is non-trivial on $K_{i}$, this involution is the field automorphism of order 2 on each of the $K_{i}$. To apply Proposition 2.4 it is hence enough to determine the parity of the number of composition factors of the $A$-module $W(\mathbf{k})$. If $d:=\left[\mathbb{F}_{q}: \mathbb{F}(\mathbf{k})\right]=2^{a} b$ with $a \geq 1$ and $b$ odd then

$$
\begin{equation*}
2^{a+1} \text { is the 2-part of }\left[K_{i}: \mathbb{F}(\mathbf{k})\right] \text { for all } i \tag{2}
\end{equation*}
$$

because the subfields of 2-power index of $\mathbb{F}_{q^{2}}$ are linearly ordered.
As $\mathbf{k}$ consists of the $d$-fold juxtaposition of a squence of length $f / d$ and one of the $k_{i}$ is odd, at least $d$ of the $k_{i}$ are odd and hence

$$
\begin{equation*}
\operatorname{dim}(W(\mathbf{k}))=\prod_{i=0}^{f-1}\left(k_{i}+1\right) \tag{3}
\end{equation*}
$$

is divisible by $2^{d}$.
So the number of composition factors of $V$ is odd, if and only if $2^{a+1}$ is the maximal 2-power that divides $\operatorname{dim}(W(\mathbf{k}))$. In particular,

$$
a+1 \geq d=2^{a} b
$$

which implies that $a=1=b$, i.e. $d=2$, so $\mathbb{F}(\mathbf{k})=\mathbb{F}_{p^{f / 2}}$. Moreover $\operatorname{dim}(W(\mathbf{k})) \equiv 4$ $(\bmod 8)$.
