1.1 The local-global principle

This Habilitation thesis investigates the local-global principle for quadratic and hermitian forms over the ring of integers in number fields. Let $K$ be a number field with ring of integers $\mathfrak{o}$. The local-global principle shows up in various situations, for example:

- The Hasse-Minkowski theorem states that a quadratic form over $K$ is isotropic, i.e. it represents 0, if and only if it is isotropic over every completion of $K$. As a consequence, two quadratic forms over $K$ are isometric if and only if their completions are isometric at every place of $K$.

- The same result also holds for (quaternionic) hermitian spaces over number fields. More generally it extends to simply-connected algebraic groups defined over $K$.

- The Hasse-Brauer-Noether-Albert theorem (c.f. [Rei03, Theorem 32.11]) states that a central-simple $K$-algebra is split, i.e. isomorphic to a full matrix ring $K^{m\times m}$ if and only if it splits over every completion of $K$. As a consequence, two central simple $K$-algebras are isomorphic if and only if their completions are isomorphic at every place of $K$.

- The Local-Square theorem states that an element $a \in K$ is a square if and only if $a$ is a square in every completion of $K$. Note that the result is not completely true for higher powers as the Grunwald-Wang theorem shows.

- The Hasse norm theorem states that given a cyclic field extension $F/K$, then $a \in K$ is a global norm in $F/K$ if and only if for each place $v$ of $K$ and a place $w$ of $F$ over $v$, $a$ is a local norm in $F_w/K_v$. Again, the result does not hold for arbitrary extensions $F/K$, not even for abelian ones.

- Two $\mathfrak{o}$-lattices, i.e. finitely generated $\mathfrak{o}$-submodules of a vector space over $K$ are equal if and only if their completions are equal at every place of $K$.

For arithmetic structures, the local-global principle usually fails. For example, let $\mathcal{I}(\mathfrak{o})$ be the group of fractional ideals of $\mathfrak{o}$. Every element in $\mathcal{I}(\mathfrak{o})$ is locally principal, but not necessarily principal itself. If the local-global principle fails, it is interesting to know ‘by how much it fails’. So in the case of fractional ideals, one investigates the class group $\text{Cl}(\mathfrak{o}) := \mathcal{I}(\mathfrak{o})/\{a\mathfrak{o} : a \in K^*\}$.

1 Introduction

1.2 Hermitian lattices and genera

Let $E/K$ be a field extension of degree at most 2 or let $E$ be a quaternion skewfield over $K$. The canonical involution of $E/K$ will be denoted by $\overline{\cdot}: E \to E$. A hermitian space over $E$ is a (left) vector space $V$ over $E$ equipped with a sesquilinear form $\Phi: V \times V \to E$ such that

- $\Phi(x + x', y) = \Phi(x, y) + \Phi(x', y)$ for all $x, x', y \in V$.
- $\Phi(\alpha x, \beta y) = \alpha \Phi(x, y) \overline{\beta}$ for all $x, y \in V$ and $\alpha, \beta \in E$.
- $\Phi(y, x) = \overline{\Phi(x, y)}$ for all $x, y \in V$.

If $E = K$ the above setting simply gives a quadratic space over $K$.

Let $\mathcal{O}$ be a maximal order in $E$. An $\mathcal{O}$-lattice in $V$ is a finitely generated $\mathcal{O}$-module that contains an $E$-basis of $V$. The local-global principle does not hold for $\mathcal{O}$-lattices in general. As in the case of fractional ideals of $\mathfrak{o}$, this immediately leads to the definition of the genus. Two $\mathcal{O}$-lattices $L, M$ in $V$ are said to be in the same genus if and only if the completions $L_p := L \otimes_{\mathcal{O}} \mathcal{O}_p$ and $M_p$ are isometric for every prime ideal $p$ of $\mathfrak{o}$. Each genus is a disjoint union of (finitely many) isometry classes. The number of isometry classes in a genus is called its class number. So again, the class number measures ‘by how much’ the local global principle fails. In particular, the one-class genera consist precisely of those lattices for which the local-global principle does hold.

The class number of a lattice in an indefinite hermitian space is known a priori thanks to strong approximation, see Chapter 5 for details. It only depends on some local data as well as some quotient of a ray class group. For lattices in definite spaces, such local considerations do not yield the class number of a lattice. It has to be worked out explicitly, for example using Kneser’s neighbour method.

The goal of this Habilitation project is to provide a complete classification of all definite hermitian lattices with class number one or two. It should be stressed that the field $K$, the extension $E$ and the rank $m$ of $V$ over $E$ are not fixed a priori. However, it is well known that up to a suitable equivalence relation, there are only finitely many such genera.

The enumeration of one-class genera actually dates back to C. F. Gauß. He relates the class numbers of definite binary quadratic lattices to relative ideal class numbers of CM-fields. In particular, the complete, unconditional classification of binary quadratic lattices with class number one is out of reach with current methods.

The classification of all rational quadratic lattices with class number one and rank at least three is originally due to G. L. Watson who classified these lattices by hand in a long series of papers [Wat63, Wat72, Wat74, Wat78, Wat82, Wat84, Wat]. In [KL13], D. Lorch and the author checked Watson’s computations using the algorithms given in Chapter 6 and found them to be largely correct. They also enumerate all one-class genera in dimensions four and five, for which G. Watson only produced partial results. Very recently, D. Lorch in his thesis [Lor] (supervised by the author) successfully extends this classification to all one-class genera over totally real number fields.

For $E \neq K$, no complete classifications were previously known.
1.3 Limitations

The main strategy of the classification of all genera of definite hermitian lattices with given class number is as follows.

1. Enumerate the possible totally real number fields $K$, the possible $K$-algebras $E$ and the possible ranks $m$.

2. Enumerate the possible similarity classes of hermitian spaces of rank $m$ over $E$.

3. Enumerate the genera of square-free lattices with class number at most $B$. Square-free (or almost unimodular lattices as they are called by some authors) are those lattices that are endpoints under some reduction operators which do not increase class numbers, see Section 6.1 for details.

4. Enumerate the similarity classes of all genera with class number at most $B$ by inspecting inverse images under these reduction operators.

Steps 2–4 never pose a problem. However, the first step might simply be impossible to do in practice. The reason is as follows. Siegel’s mass formula yields upper bounds on the root discriminant of the possible totally real base fields $K$. Then one looks up these fields in tables such as [Voi08]. However, these tables are only complete up to root discriminant 14 (without further additional information like the number of primes ideals of norm 2). Already this classification needed about 200 days of CPU time. Since the search space for these fields grows exponentially with the degree of the fields, already the enumeration of all fields with slightly larger root discriminant say 15, is completely out of reach. This is the only reason why the classification of all definite hermitian lattices with class number at most two is impossible in case of some unary and binary lattices. More precisely, the following problems occur.

1. Suppose $E = K$. As mentioned before, the binary quadratic lattices lead to relative class number problems of CM-extensions, see Section 7.2 for details. Hence this case is out of reach. However the rational binary quadratic lattices with class number at most two can be enumerated assuming the Generalized Riemann Hypothesis, see Section 7.2.2.

All definite quadratic lattices with class number at most two and rank different from two have been completely classified. A summary of the results is presented in Chapter 7.

It is worth mentioning, that the ternary quadratic case is especially challenging. Pfeuffer’s bounds on the local factors in Siegel’s mass formula show that the root discriminant of $K$ is at most 24.21, see Corollary 6.3.2. As mentioned above, this bound is useless for practical purposes.

However, there is a different way of enumerating the ternary quadratic lattices with class number at most $B$ using quaternion orders, see [KL16] and Section 7.3. The idea is as follows. The local global principle for quaternion orders also fails.
1 Introduction

Thus it is natural to define what is (for historical reasons) called the type of a quaternion order. Two orders in a quaternion algebra are said to be of the same type if and only if their completions are isomorphic (i.e. conjugate) at every prime ideal of \( \mathfrak{o} \). Again, each type of orders is a finite union of conjugacy classes and the number of such classes is called the type number. Now there are correspondences by Brzezinski-Peters-Eichler-Brandt or J. Voight between definite, ternary quadratic lattices over \( K \) and definite Gorenstein quaternion orders over \( K \) which maps genera and isometry classes to types and conjugacy classes. Hence, instead of classifying the definite quadratic \( \mathfrak{o} \)-lattices with class number at most two one can also classify the Gorenstein quaternion orders over \( K \) with type number at most two. The latter has the advantage, that one can bring Eichler’s mass formula into the game. It yields a much better bound on the root discriminant of \( K \), see Theorem 7.3.4 for details. Using this bound, one can indeed enumerate all possible base fields \( K \) that might admit one-class genera of definite quadratic forms.

It is also worth mentioning that the type number of a quaternion order agrees with the type number of its Gorenstein closure. Thus the above classification actually yields all definite quaternion orders with type number one or two, whether they are Gorenstein or not. From this result, one can then enumerate all definite quaternion orders with ideals class number one or two, see [KL16] for details.

2. Suppose \( E/K \) is a CM-extension. The unary hermitian case is directly related to the binary quadratic case. So a complete classification is again impossible. In the binary hermitian case, the situation is very similar. In this case, the possible totally real base fields \( K \) that might occur can be worked out completely, see Section 8.2. However, for some fixed field \( K \), the enumeration of all possible extensions \( E/K \) turns out to be the problem. In this case, Siegel’s mass formula does not involve the relative discriminant \( d_{E/K} \) but merely the relative class number \( \# \text{Cl}(E)/\# \text{Cl}(K) \). So again, the enumeration of all definite binary hermitian lattices is a relative class number problem, see Section 8.2 for details. However, for \( K = \mathbb{Q} \) it turns out that one needs to know the imaginary quadratic number fields \( E \) with class number at most 48. These have been computed by M. Watkins in his thesis [Wat04]. So for \( K = \mathbb{Q} \), the enumeration of all definite, binary hermitian lattices with class number at most 2 is indeed feasible, see Table 8.1 for a summary of the results.

For all lattices of rank at least 3, the classification of all definite hermitian lattices with class number at most two given in Chapter 8 is complete.

3. For quaternion algebras \( E \) over \( K \), Chapter 9 provides a complete classification of all definite hermitian lattices with class number at most two.

1.4 Results

Chapters 7 to 9 report on the classification of all definite quadratic, hermitian and quaternionic hermitian lattices respectively. Below are short summaries of the results in
1.4 Results

Theorem 1.4.1 Let $K$ be a totally real number field with maximal order $O$. Let $L$ be a definite quadratic $O$-lattice of rank $m \geq 3$.

1. If $K = \mathbb{Q}$ and $L$ has class number one, then $m \leq 10$. Up to similarity, there are 1884 definite, rational quadratic lattices with class number one and rank at least 3. This result is due to G. Watson, see also [KL13].

2. If $K = \mathbb{Q}$ and $L$ has class number two, then $m \leq 16$. Up to similarity, there exist 7283 genera of definite, rational quadratic lattices with class number one and rank at least 3.

3. If $K \neq \mathbb{Q}$ and $L$ has class number one, then $m \leq 6$. Further, if $m \in \{5, 6\}$ then $K = \mathbb{Q}(\sqrt{5})$ and for each rank $m$ there are two similarity classes. Up to similarity, there exist 4019 definite quadratic lattices over 29 different fields $K \neq \mathbb{Q}$ with class number one and rank at least 3. The largest field has degree 5. This result is due to D. Lorch, see [Lor].

4. If $K \neq \mathbb{Q}$ and $L$ has class number two, then $m \leq 8$. Up to similarity, there are 17,064 genera of definite quadratic lattices over 75 different fields $K \neq \mathbb{Q}$ with class number two and rank at least 3. The largest field has degree 6.

Details are given in Chapter 7.

Theorem 1.4.2 Let $E/K$ be a CM-extension and let $O$ be the maximal order of $E$. If $L$ is a definite hermitian $O$-lattice of rank $m \geq 3$ and class number one (two), then $m \leq 8$ ($m \leq 9$). Moreover, there are 164 (406) similarity classes of genera of such lattices over 10 (19) different fields $E$. The largest field $E$ has degree 6 (8). A complete classification is given in Chapter 8.

Theorem 1.4.3 Let $E$ be a definite quaternion algebra over some totally real number field $K$. Further let $O$ be a maximal order in $E$ and let $L$ be a hermitian $O$-lattice of rank $m$. If $L$ has class number one (two), then $m \leq 4$ ($m \leq 5$). Further, there are only 69 (148) different algebras $E$ over 29 (60) different centers $K$ that admit genera of definite lattices of class number one (two). A complete list of these lattices is given in Chapter 9.

Note that counting similarity classes of quaternionic hermitian lattices does not make much sense since two different maximal orders yield genera which can never be similar. However, these genera can be described uniformly using genus symbols, see Chapter 9 for details.

Since some enumerations produced large numbers of genera, not all of these genera could be described in the thesis explicitly. Thus all the results are also electronically available from [Kir16] in a text-based format which can be processed easily by any computer algebra system.

The enumeration of all genera with given class number relies heavily on calculations (like computing automorphism groups, isometry tests, unit and class groups of orders,
ideals and orders in quaternion algebras, computing with modules over Dedekind rings, ...) that require the use of a computer algebra system. The author has chosen to implement the classification in Magma [BCP97] as it covers most of the required basic algorithms and it is easily extensible through packages. The code for performing the classification as well as certain intermediate steps (like constructing hermitian spaces and lattices from local data, deciding (local) isometry, Kneser’s neighbour method, ...) is available upon request.

1.5 Outline

The Habilitation thesis is organized as follows. The second chapter gives a short introduction to lattices in quadratic and hermitian spaces. Chapter 3 recalls the classification of quadratic and hermitian spaces over local fields. It also discusses the structure of lattices in such spaces, i.e. Jordan decompositions.

The fourth chapter presents Siegel’s mass formula, which is the most important tool for classifying all genera with a given class number. The local factors that appear in the mass formula were not known in all cases. Especially local factors at even prime ideals are notoriously difficult to handle. Thus, in Sections 4.4 and 4.5 the local factors of unimodular quadratic lattices as well as the local factors of square-free hermitian lattices at ramified prime ideals over 2 are worked out completely using a method of M. Eichler.

In Chapter 5, Kneser’s Neighbour method is presented. It allows the complete enumeration of all isometry classes in a given genus. The description given here works for quadratic as well as (quaternionic) hermitian lattices. It is very explicit, in the sense that it provides generators for every single neighbour. Also the number of neighbours is worked out in all cases.

Chapter 6 explains how to classify all definite hermitian lattices with a given class number. As mentioned before, Chapters 7 to 9 report on the classification of all one- and two-class genera of lattices in definite quadratic, hermitian and quaternionic hermitian spaces respectively.

The concept of genera and isometry classes can be generalized to algebraic groups over $K$. In that sense, the first nine chapters dealt with classical (i.e. orthogonal and unitary) groups. The last chapter then discusses the parahoric subgroups of exceptional algebraic groups over $K$ having class number one.
2 Basic definitions

2.1 Quadratic and hermitian spaces

In this work, $K$ always denotes some field of characteristic 0. Further, $(E, \overline{\cdot})$ will be one of the following $K$-algebras with involution:

1. $E = K$ and $\overline{\cdot}$ is the identity on $K$.
2. $E \cong K[X]/(X^2 - a)$ and $\overline{\cdot}$ is the nontrivial $K$-linear automorphism of $E$.
3. $E$ is a quaternion algebra with center $K$, i.e. a 4-dimensional, central simple $K$-algebra. By the Artin-Wedderburn theorem, $E$ is either a skew field or isomorphic to the full matrix ring $K^{2 \times 2}$. In any case, it admits a $K$-basis $(1, i, j, ij)$ such that $a := i^2 \in K$, $b := j^2 \in K$ and $ij = -ji$.

The quaternion algebra over $K$ with these multiplication rules will be denoted by $(a, b)_K$. Further,

$$\overline{\cdot} : E \to E, x + yi + zj + wij \mapsto x - yi - zj - wij$$

with $x, y, z, w \in K$

is called the canonical involution of $E$. It satisfies $\{\alpha \in E; \alpha = \overline{\alpha}\} = K$. In particular, the reduced norm and reduced trace

$$\text{nr}_{E/K} : E \to K, \alpha \mapsto \alpha \overline{\alpha} \quad \text{and} \quad \text{tr}_{E/K} : E \to K, \alpha \mapsto \alpha + \overline{\alpha}$$

take values in $K$.

In any of these three cases, let

$$N : E \to K, \alpha \mapsto \alpha \overline{\alpha} \quad \text{and} \quad T : E \to K, \alpha \mapsto \alpha + \overline{\alpha}.$$ 

If $E = K$ these maps are simply squaring and multiplication by 2 respectively. In the other two cases these are the (reduced) norm and (reduced) trace of $E$ over $K$. Also note that since $E$ is a separable $K$-algebra, the bilinear form

$$E \times E \to K, (\alpha, \beta) \mapsto T(\alpha \beta)$$

associated to $T$ is non-degenerate.

**Definition 2.1.1** A hermitian space $(V, \Phi)$ over $E$ is a finitely generated, free left $E$-module $V$ equipped with a map $\Phi : V \times V \to E$ such that
\begin{itemize}
    \item $\Phi(x + x', y) = \Phi(x, y) + \Phi(x', y)$ for all $x, x', y \in V$.
    \item $\Phi(\alpha x, \beta y) = \alpha \Phi(x, y) \beta$ for all $x, y \in V$ and $\alpha, \beta \in E$.
    \item $\Phi(y, x) = \overline{\Phi(x, y)}$ for all $x, y \in V$.
\end{itemize}

For a hermitian space $(V, \Phi)$ over $E$, the map

$$Q_\Phi : V \to K, \ x \mapsto \Phi(x, x)$$

defines a quadratic form on the $K$-vector space $V$, i.e.

1. $Q_\Phi(ax) = a^2 Q_\Phi(x)$ for all $a \in K$ and $x \in V$,  
2. $b_\Phi : V \times V \to K, \ (x, y) \mapsto Q_\Phi(x + y) - Q_\Phi(x) - Q_\Phi(y)$ is bilinear.

In particular, if $E = K$, then $2\Phi = b_\Phi$. So in this case it makes sense to call $(V, \Phi)$ a quadratic space. Since the characteristic of $K$ is different from 2, the bilinear form $\Phi$ can be recovered from $Q_\Phi$ or $b_\Phi$ and vice versa. So in the sequel, the space $(V, \Phi)$ will also be denoted by $(V, Q_\Phi)$ whenever convenient.

**Definition 2.1.2** The hermitian spaces $(V, \Phi)$ and $(V', \Phi')$ over $E$ are said to be isometric (denoted by $(V, \Phi) \cong (V', \Phi')$), if there exists some isomorphism $\sigma : V \to V'$ of $E$-modules such that $\Phi(x, y) = \Phi'(\sigma(x), \sigma(y))$ for all $x, y \in V$. Any such isomorphism is then called an isometry between $(V, \Phi)$ and $(V', \Phi')$. The group of all isometries of $(V, \Phi)$ itself, i.e.

$$U(V, \Phi) := \{ \sigma \in \text{GL}(V) ; \Phi(\sigma(x), \sigma(y)) = \Phi(x, y) \text{ for all } x, y \in V \}$$

is called the unitary group of $(V, \Phi)$. If $(V, \Phi)$ is quadratic, then $U(V, \Phi)$ is also called the orthogonal group of $(V, \Phi)$ and will sometimes be denoted by $O(V, \Phi)$.

**Definition 2.1.3** Let $(V, \Phi)$ be a hermitian space over $E$ of rank $m$ with basis $B$.

1. The space $(V, \Phi)$ is called regular, if $\Phi(x, V) \neq \{0\}$ for all nonzero $x \in V$.

2. The space $(V, \Phi)$ is said to represent $a \in K$, if $a = Q_\Phi(x)$ for some non-zero $x \in V$. A vector $x \in V$ is called isotropic if $Q_\Phi(x) = 0$. Similarly, $(V, \Phi)$ is said to be isotropic, if $\Phi$ represents zero, i.e. it contains a nonzero isotropic vector.

3. Two vectors $x, y \in V$ are called perpendicular or orthogonal if $\Phi(x, y) = 0$. Let $V_1, V_2$ be $E$-submodules of $V$. Then $V$ is the orthogonal sum of the $V_i$, denoted by $V = V_1 \perp V_2$, if $V = V_1 \oplus V_2$ and $\Phi(V_1, V_2) = \{0\}$.

4. The Gram matrix of any tuple $S = (x_1, \ldots, x_m) \in V^m$ is

$$G(S) := (\Phi(x_i, x_j))_{i,j} \in E^{m \times m}.$$
5. The determinant \( \det(V, \Phi) \) is the class of the Dieudonné determinant \( \det(G(B)) \) in \( K/N(E^*) \) whenever \( E \) is a skew field. If \( E \) contains zero divisors, then \( \det(V, \Phi) \) is defined to be the neutral element in the trivial group \( K^*/N(E^*) \). In any case,

\[
\text{disc}(V, \Phi) := (-1)^{m(m-1)/2} \cdot \det(V, \Phi)
\]

is called the discriminant of \((V, \Phi)\).

6. Given square matrices \( G_1, \ldots, G_s \) over \( E \) such that \( G_i = G_i^\text{tr} \), then \( \langle G_1, \ldots, G_s \rangle \) denotes a hermitian space over \( E \) which has a block diagonal Gram matrix \( \text{Diag}(G_1, \ldots, G_s) \).

7. The space \((V, \Phi)\) is said to be hyperbolic, if \((V, \Phi) \cong \langle (0 1 \quad 1 0), \ldots, (0 1 \quad 1 0) \rangle\).

The fact that the bilinear form associated to \( T \) is non-degenerate has several important consequences.

**Theorem 2.1.4** Let \((V, \Phi)\) be a regular hermitian space over \( E \). Then \((V, \Phi)\) admits an orthogonal \( E \)-basis, i.e. \((V, \Phi) \cong (a_1, \ldots, a_m)\) for some \( a_i \in K^* \).

**Proof.** Let \((b_1, \ldots, b_m)\) be any basis of \( V \). The result is trivial if \( m = 1 \). Suppose now \( m \geq 2 \) and \( Q_\Phi(b_i) = 0 \) for all \( i \). Since \((V, \Phi)\) is non-degenerate there exists \( i > 1 \) such that \( \Phi(b_i, b_1) \neq 0 \). Since the trace bilinear form associated to \( T \) non-degenerate, there exists some \( \lambda \in E \) such that \( T(\Phi(b_1, b_1)X) = 1 \). Then \( Q_\Phi(b_1 + \lambda b_i) = T(\Phi(b_1, \lambda b_2)) = 1 \). So without loss of generality one may assume that \( a_1 := Q_\Phi(b_1) \neq 0 \). But then \( V = Eb_1 \perp \sum_{j=2}^{m} E(b_j - \frac{\Phi(b_j, b_1)}{a_1} b_1) \). Hence the result follows by induction on \( m \). \( \square \)

**Proposition 2.1.5** Let \((V, \Phi)\) be a regular hermitian space over \( E \) of rank \( m \). Let \( \mathbb{H} = \left( \frac{-1}{-1} \right) \) be Hamilton’s quaternions.

1. If \( K = \mathbb{R} \) and \( E \in \{ \mathbb{R}, \mathbb{C}, \mathbb{H} \} \) then the isomorphism type of a regular hermitian space over \( E \) is uniquely determined by its rank and \( n_{(V, \Phi)} := \# \{ b \in B ; Q_\Phi(b) < 0 \} \) where \( B \) denotes any orthogonal basis of \( V \) over \( E \).

2. If \( N(E^*) = K^* \), then \((V, \Phi) \cong (1, \ldots, 1)\). Note that this holds whenever \( K = \mathbb{C} \).

**Proof.** The first assertion is Sylvester’s law of inertia. The second assertion follows from the previous theorem and the fact that \( \Phi(\alpha x, \alpha x) = N(\alpha)\Phi(x, x) \) for all \( \alpha \in E \) and \( x \in V \). \( \square \)

**Remark 2.1.6** Let \((V, \Phi)\) be a hermitian space over \( E \). For any \( E \)-linear map \( \sigma : V \rightarrow V \), the following statements are equivalent:

1. \( \sigma \in U(V, \Phi) \).
2. \( Q_\Phi(\sigma(x)) = Q_\Phi(x) \) for all \( x \in V \).
2 Basic definitions

Proof. Clearly 1. implies 2. Conversely, suppose $\sigma$ satisfies the second condition. If $E = K$, then 1. holds thanks to the polarization identity

$$2\Phi(x, y) = b_\Phi(x, y) = Q_\Phi(x + y) - Q_\Phi(x) - Q_\Phi(y)$$

for all $x, y \in V$.

Suppose now $E \neq K$. Let $x, y \in V$ and $\alpha \in E$. By assumption

$$Q_\Phi(\sigma(x)) + Q_\Phi(\sigma(y)) + T(\Phi(\sigma(x), \sigma(y))) = Q_\Phi(\sigma(x + y)) = Q_\Phi(x + y)$$

$$= Q_\Phi(x) + Q_\Phi(y) + T(\Phi(x, y)),$$

and therefore

$$T(\alpha \Phi(\sigma(x), \sigma(y))) = T(\alpha \Phi(x, y))$$

for all $\alpha \in E$.

The bilinear form associated to $T$ is non-degenerate and thus $\Phi(x, y) = \Phi(\sigma(x), \sigma(y))$. □

2.2 Lattices over maximal orders

In this section, some well known facts about finitely generated, torsion free modules over maximal orders are recalled.

Definition 2.2.1 Let $\mathfrak{o}$ be a Dedekind ring, i.e. an integrally closed Noetherian ring of Krull dimension 1. Further, let $K$ be the field of fractions of $\mathfrak{o}$ and let $E$ be a separable $K$-algebra.

1. An $\mathfrak{o}$-lattice $I \subseteq E$ is a finitely generated $\mathfrak{o}$-submodule of $E$. It is said to be full, if the ambient $K$-space $KI$ equals $E$.

2. A full $\mathfrak{o}$-lattice in $E$ which is also a subring of $E$ is called an $\mathfrak{o}$-order (or simply an order) in $E$. An order is called maximal, if it is not properly contained in another order.

3. Let $I$ be a full $\mathfrak{o}$-lattice in $E$. Then

$$O_\ell(I) := \{x \in E ; xI \subseteq I\} \quad \text{and} \quad O_r(I) := \{x \in E ;Ix \subseteq I\}$$

are $\mathfrak{o}$-orders in $E$, the so-called left and right orders of $I$. The lattice $I$ is integral, if $I \subseteq O_\ell(I)$ (or equivalently $I \subseteq O_r(I)$).

4. Let $\mathcal{O}$ be an order in $E$. An $\mathfrak{o}$-lattice $I$ is called a fractional left ideal of $\mathcal{O}$, if $O_\ell(I) \subseteq \mathcal{O}$. Similarly, one defines fractional right ideals. If $I$ as a fractional left and right ideal of $\mathcal{O}$, it is called a fractional twosided ideal of $\mathcal{O}$.

5. A fractional left ideal $I$ of $\mathcal{O}$ is said to be invertible, if $IJ = \mathcal{O}$ for some $\mathfrak{o}$-lattice $J$. If $J$ exists, then $\mathcal{O} = O_\ell(I)$ and $JI = O_r(I)$. So there is no need to distinguish between left, right and twosided invertible ideals. Also note that if $\mathcal{O}$ is maximal, then every (left/right/twosided) ideal of $\mathcal{O}$ is invertible.
Definition 2.2.2 Let $\mathcal{O}$ be a maximal order in some separable $K$-algebra $E$ and let $V$ be a finitely generated, free left module over $E$.

1. An $\mathcal{O}$-lattice $L \subset V$ is a finitely generated $\mathcal{O}$-module in $V$. The rank of an $\mathcal{O}$-lattice $L$ is the rank of the ambient space $EL$ over $E$ and will be denoted by $\text{rank}(L)$. The lattice $L$ is said to be full, if the ambient space $EL$ equals $V$, i.e. $L$ contains an $E$-basis of $V$.

2. Let $L$ be an $\mathcal{O}$-lattice. Suppose there exists an $E$-basis $(x_1, \ldots, x_n)$ of $EL$ and fractional left ideals $\mathfrak{A}_1, \ldots, \mathfrak{A}_n$ of $\mathcal{O}$ such that

$$L = \bigoplus_{i=1}^{n} \mathfrak{A}_i x_i.$$

Then the sequence of pairs $(\mathfrak{A}_i, x_i)_{1 \leq i \leq n}$ is called a pseudo-basis of $L$.

The existence of pseudo-bases over Dedekind rings is due to E. Steinitz and is well known.

Theorem 2.2.3 (Steinitz) Let $\mathfrak{o}$ be a Dedekind ring with fields of fractions $K$ and let $M$ be an $\mathfrak{o}$-lattice in a finite dimensional $K$-space $V$.

1. The $\mathfrak{o}$-module $M$ is projective and admits some pseudo-basis $(a_i, x_i)_{1 \leq i \leq r}$.

2. Let $M'$ be an $\mathfrak{o}$-lattice in $KM$ of rank $s$. Then $s \leq r$ and there exists a pseudo-basis $(a_i, x_i)_{1 \leq i \leq r}$ of $M$ and fractional ideals $b_1, \ldots, b_s$ of $\mathfrak{o}$ such that

$$M' = \bigoplus_{j=1}^{s} b_j a_j x_j \quad \text{and} \quad b_1 \supseteq b_2 \supseteq \ldots \supseteq b_s.$$

The ideals $b_1, \ldots, b_s$ are called the invariant factors of $M$ and $M'$; they are uniquely determined. In particular, the index ideal of $M'$ in $M$

$$[M : M']_{\mathfrak{o}} := \prod_{i=1}^{s} b_i$$

is well defined.

Proof. See for example [O'M73, Chapter 81].

Using pseudo-bases, Magma can perform a wide range of operations for finitely generated modules over Dedekind rings like addition, intersection, comparison, invariant factors, etc. Hence, for algorithmic purposes, lattices over Dedekind rings will always be assumed to be given by a pseudo-basis.

For the remainder of this section let $\mathfrak{o}$ be the ring of integers of some number field $K$ and let $\mathcal{O}$ be a maximal order in some separable $K$-algebra $E$. Then every $\mathcal{O}$-lattice admits
a pseudo-basis, see for example [Rei03, Theorem 2.44 and Remark 2.45]. However, I do not know of a constructive proof of this fact in the literature or even an implementation in some computer algebra system. Hence a constructive proof will be given below. The algorithm is based on the corresponding algorithm for finitely generated modules over Dedekind rings by W. Bosma and M. Pohst [BP91].

First, one needs special two-element generators for (left) ideals of $\mathcal{O}$:

**Lemma 2.2.4** Let $\mathfrak{A}$ be an integral left ideal of $\mathcal{O}$. Let $a \in \mathbb{N}$ be a generator of $\mathfrak{A} \cap \mathbb{Z}$. Then there exists some $\alpha \in \mathfrak{A}$ such that

\[ \mathfrak{A} = \mathcal{O}a + \mathcal{O}\alpha \quad \text{and} \quad \mathcal{O}\alpha \cap \mathbb{Z} = \mathbb{Z}ab \text{ where } b \in \mathbb{N} \text{ is coprime to } a. \]

Further, if $a$ and $\alpha$ satisfy the above conditions, then $\mathfrak{A}^{-1} = \mathcal{O} + a^{-1}b\mathcal{O}$.

**Proof.** If $a = 1$, then $\mathfrak{A} = \mathcal{O}$ and one can take $\alpha = 1$. Suppose now $a > 1$. By [Rei03, Corollary 27.7], there exists some $\alpha \in E^*$ such that $\mathfrak{A}^{-1}a^2 + \mathfrak{A}^{-1}\alpha = \mathfrak{A}^{-1} \mathfrak{A}$. Hence $\mathfrak{A} = \mathcal{O}a^2 + \mathcal{O}\alpha = \mathcal{O}a + \mathcal{O}\alpha$. By induction it follows that $\mathfrak{A} = \mathcal{O}a^n + \mathcal{O}\alpha$ for all $n \in \mathbb{N}$. Let $\mathcal{O}\alpha \cap \mathbb{Z}$ be generated by $ab \in \mathbb{N}$. Suppose there exists some prime divisor $p$ of $\gcd(a, b)$. Then there exists some prime ideal $\mathfrak{p}$ of $\mathcal{O}$ such that $a$ is not contained in $\mathfrak{p} \alpha$. Further, there exists some $n \in \mathbb{N}$ such that $\mathfrak{p}a^n \subseteq \mathfrak{p} \alpha$ and therefore $\mathfrak{A}_p = \mathfrak{p} \alpha$. But then $a \in \mathfrak{O_p} \alpha$ gives the desired contradiction. Hence $a$ and $b$ are coprime.

Suppose now $\alpha \in \mathcal{O}$. Then $\mathfrak{B} = \mathcal{O} + a^{-1}b\mathcal{O}$. Then $\mathfrak{BA} = \mathcal{O}a + \mathcal{Ob} + \mathcal{O}\alpha \mathcal{O} + \mathcal{O}^{-1}ab\mathcal{O}$. It follows that $\mathfrak{BA} = \mathcal{O}$ since $a$ and $b$ are coprime integers and $\alpha, \alpha^{-1}ab \in \mathcal{O}$. Thus $\mathfrak{B} = \mathfrak{A}^{-1}$ as claimed. \hfill $\Box$

Note that, an element $\alpha$ satisfying the conditions of Lemma 2.2.4 is usually found as a small linear combination of some $\mathbb{Z}$-basis of $\mathfrak{A}$.

**Corollary 2.2.5** If $\mathfrak{A}$ is a left ideal of $\mathcal{O}$, then there exist $\alpha_1, \alpha_2 \in \mathfrak{A}$ and $\beta_1, \beta_2 \in \mathfrak{A}^{-1}$ such that $\alpha_1\beta_1 + \alpha_2\beta_2 = \beta_1\alpha_1 + \beta_2\alpha_2 = 1$.

**Proof.** Without loss of generality, $\mathfrak{A}$ is integral. Let $a, b, \alpha$ be as in Lemma 2.2.4. Since $a$ and $b$ are coprime integers, there exist $r, s \in \mathbb{Z}$ such that $ra + sb = 1$. Then for example $\beta_1 = 1$, $\alpha_1 = ra$, $\beta_2 = s\alpha^{-1}$ and $\alpha_2 = \alpha$ will do the trick. \hfill $\Box$

**Algorithm 2.2.6** PSEUDOBSIS$(m_1, \ldots, m_r)$

**Input:** Generators $m_1, \ldots, m_r$ of some left $\mathcal{O}$-module $M$.

**Output:** Some pseudo-basis $(\mathfrak{A}_i, x_i)_i$ of $M$.

1: Let $(v_1, \ldots, v_n)$ be an $E$-basis of the ambient space $EM$.
2: if $n = 0$ then return $\emptyset$ end if
3: Write $m_i = v_{i,1}v_1 + \cdots + v_{i,n}v_n$ for $1 \leq i \leq r$.
4: Set $\mathfrak{A}_1 = \sum_{i=1}^r \mathcal{O}v_{i,1}$.
5: Compute $\alpha_1, \alpha_2 \in \mathfrak{A}_1$ and $\beta_1, \beta_2 \in \mathfrak{A}_1^{-1}$ such that $\beta_1\alpha_1 + \beta_2\alpha_2 = 1$.
6: Using linear algebra over $\mathfrak{o}$ or $\mathbb{Z}$, compute $h_1, h_2 \in M$ and $w_1, w_2 \in \bigoplus_{j \geq 2} E v_j$ such that $\alpha_iv_1 = h_i + w_i$. 

16
Proof. By construction, \( m'_j \in M \) and \( m'_j - m_j = \nu_{i,1}x_i \in \mathfrak{A}_i x_1 \subseteq M \). Thus \( M \) equals \( \mathfrak{A}_1 x_1 \oplus \sum_{j=1}^{r} \mathcal{O}m'_j \). By induction on \( \text{rank}(M) \), the algorithm terminates and returns a pseudo-basis of \( M \).

Let \( p \) be a prime ideal of \( \mathfrak{a} \). Given an \( \mathfrak{a} \)-module \( M \), let \( M_p \) denote its completion at \( p \). Using pseudo-bases, one can not only perform the obvious operations like taking sums, intersections, etc., but also various ‘local’ manipulations of a given \( \mathcal{O} \)-module \( M \). Usually, one proceeds in three steps:

1. Construct a free \( \mathcal{O} \)-submodule (or supermodule) \( M' \) of \( M \) such that \( M_p = M'_p \) for some prime ideal \( p \) of \( \mathfrak{a} \).
2. Using the \( \mathcal{O} \)-basis of \( M' \) (which is also a \( \mathcal{O}_p \)-basis for \( M_p \)) perform the wanted local operation on \( M_p \).
3. By adding the module \( pM \) and intersecting with \( p^{-1}M \), one ensures that the places different from \( p \) are not affected by the manipulations performed in step 2.

For example, the construction of maximal submodules can be done as follows.

**Algorithm 2.2.7** MAXIMALSUBMODULES(\( M, p \))

**Input:** An \( \mathcal{O} \)-module \( M \) given by some pseudo-basis \( (\mathfrak{A}_1, x_1), \ldots, (\mathfrak{A}_s, x_s) \) and some prime ideal \( p \) of \( \mathfrak{a} \).

**Output:** The set of all maximal \( \mathcal{O} \)-sublattices of \( M \) that contain \( pM \).

1. For \( 1 \leq i \leq s \) compute \( \alpha_i \in \mathfrak{A}_i \) such that \((\mathfrak{A}_i)_p = \mathcal{O}_p \alpha_i \) (for example by inspecting small linear combinations of elements in a \( \mathcal{Z} \)-basis of \( \mathfrak{A}_i \)).
2. Let \( M' := \sum_{i=1}^{s} \mathcal{O}\alpha_i x_i \subseteq M \).
3. Let \( \varphi: M' \to (\mathcal{O}/p\mathcal{O})^s, \sum_{i} \lambda_i x_i \mapsto (\lambda_1 + p\mathcal{O}, \ldots, \lambda_1 + p\mathcal{O}) \).
4. Let \( X_1, \ldots, X_r \) be the maximal \( \mathcal{O}/p\mathcal{O} \)-submodules of \( (\mathcal{O}/p\mathcal{O})^s \).
5. return \( \{\varphi^{-1}(X_i) + pM; 1 \leq i \leq r\} \).

**Proof.** From \( M_p = M'_p \), it follows that \((\varphi^{-1}(X_i) + pM)_p = (\varphi^{-1}(X_i))_p \) with \( 1 \leq i \leq r \) are the maximal \( \mathcal{O}_p \)-submodules of \( M_p \) that contain \( pM \). Let \( q \) be a prime ideal of \( \mathfrak{a} \) different from \( p \). Then \( M' \subseteq M \) implies that \((\varphi^{-1}(X_i) + pM)_q = M_q \). Hence the result is correct.

### 2.3 Hermitian lattices over Dedekind rings

Let \( \mathfrak{a} \) be a Dedekind ring with field of fractions \( K \). Further let \((V, \Phi)\) be a regular hermitian space over \( E \) and fix some maximal \( \mathfrak{a} \)-order \( \mathcal{O} \) in \( E \).

To ease notation, the term ‘\( \mathcal{O} \)-lattice in \((V, \Phi)\)’ from now on means an \( \mathcal{O} \)-lattice in \( V \) of full rank.
2 Basic definitions

Definition 2.3.1 Let $\mathfrak{A}$ be a fractional left ideal of $\mathcal{O}$. Then $N(\mathfrak{A})$ and $T(\mathfrak{A})$ denote the $\mathfrak{o}$-ideals generated by \(\{\alpha \mathfrak{A}; \alpha \in \mathfrak{A}\}\) and $\{\alpha + \mathfrak{A}; \alpha \in \mathfrak{A}\}$ respectively.

Definition 2.3.2 Let $L$ be a free $\mathcal{O}$-lattice in $(V, \Phi)$ with basis $B$. Suppose $E$ is a skew field. Then

\[
det(L) := \det(G(B)) \in K^*/N(\mathcal{O}^*)
\]
\[
disc(L) := (-1)^{m(m-1)/2} \cdot \det(L)
\]

are called the determinant and discriminant of $L$ respectively. Given square matrices $G_1, \ldots, G_s$ over $E$ such that $G_i = G_i^{\text{tr}}$, then $\langle G_1, \ldots, G_s \rangle$ denotes a free hermitian $\mathcal{O}$-lattice with Gram matrix $\text{Diag}(G_1, \ldots, G_s)$.

Definition 2.3.3 Let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$.

1. Then $L^\# := \{x \in V; \Phi(x, L) \subseteq \mathcal{O}\}$ is called the dual of $L$.
2. $L$ is called integral if $L \subseteq L^\#$.
3. If there exists some fractional twosided ideal $\mathfrak{A}$ of $\mathcal{O}$ such that $\mathfrak{A}L^\# = L$, then $L$ is said to be $\mathfrak{A}$-modular. The $\mathcal{O}$-modular lattices are also called unimodular.
4. If $E$ is commutative, then the index ideal $[L^\# : L]_\mathcal{O}$ is called the volume of $L$ and will be denoted by $v(L)$.
5. The scale $\mathfrak{s}(L)$ is the set $\Phi(L, L) = \{\Phi(x, y); x, y \in L\}$.
6. The $\mathfrak{o}$-ideal generated by $\{Q_\Phi(x); x \in L\}$ is the norm $n(L)$.
7. Let $\mathfrak{a}$ be a fractional ideal of $\mathfrak{o}$. Then $L$ is said to be $\mathfrak{a}$-maximal, if $n(L) \subseteq \mathfrak{a}$ and whenever $L \subseteq L'$ for some $\mathcal{O}$-lattice $L'$ then $n(L') \not\subseteq \mathfrak{a}$.
8. Given a fractional left ideal $\mathfrak{A}$ of $\mathcal{O}$, let

\[
L^\mathfrak{A} := \{x \in L; \Phi(x, L) \subseteq \mathfrak{A}\}
\]

9. For $a \in K^*$, the rescaled lattice $L^a$ denotes the module $L$ in the hermitian space $(V, a\Phi)$.
10. Suppose $L = L_1 \oplus L_2$ with some $\mathcal{O}$-submodules $L_i$ such that $\Phi(L_1, L_2) = \{0\}$. Then $L$ is called the orthogonal sum of $L_1$ and $L_2$. This will be denoted by $L = L_1 \perp L_2$.

Remark 2.3.4 Let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$ with pseudo-basis $(\mathfrak{A}_i, x_i)_{1 \leq i \leq m}$.

1. Let $(x_1^*, \ldots, x_m^*)$ be the basis of $V$, which is dual to $(x_1, \ldots, x_m)$ with respect to $\Phi$. Then

\[
L^\# = \bigoplus_{i=1}^m \mathfrak{A}_i^{-1} x_i^*.
\]

In particular, $L^\#$ is an $\mathcal{O}$-lattice with pseudo-basis $(\mathfrak{A}_i^{-1}, x_i^*)_{1 \leq i \leq m}$ and $(L^\#)^\# = L$.  

18
2. The scale $s(L)$ is a twosided ideal of $\mathcal{O}$. Moreover, the scale and norm of $L$ can be computed as follows:

$$s(L) = \sum_{1 \leq i, j \leq m} A_i \Phi(x_i, x_j) \overline{A_j},$$

$$n(L) = \sum_{i=1}^{m} N(A_i) \Phi(x_i, x_i) + \sum_{1 \leq i < j \leq m} T(A_i \Phi(x_i, x_j) A_j).$$

3. If $E$ is a field, then the volume $v(L)$ is the fractional ideal of $E$ generated by

$$\{\det(G(b)) : b \subset L \text{ is linearly independent}\}.$$

4. Suppose $L$ is $\mathfrak{A}$-modular. Then $\mathfrak{A} = s(L)$, in particular, it make sense to call $L$ a modular lattice, since the ideal $\mathfrak{A}$ can be recovered easily from $L$.

Proof. After taking completions, one may assume that $L$ is a free $\mathcal{O}$-module. The proofs are then routine. □

Definition 2.3.5 Let $(V', \Phi')$ be a hermitian space over $E$. Let $L$ and $L'$ be $\mathcal{O}$-lattices in $(V, \Phi)$ and $(V', \Phi')$ respectively.

1. The lattices $L$ and $L'$ are isometric, denoted by $L \cong L'$, if $\sigma(L) = L'$ for some isometry $\sigma: (V, \Phi) \to (V', \Phi')$. Then $\sigma$ is called a isometry from $L$ to $L'$.

2. The lattices $L$ and $L'$ are said to be similar, if $L' \cong L^a$ for some $a \in K^\ast$.

3. The automorphism group of $L$ is the group

$$\text{Aut}(L) := \{\sigma \in U(V, \Phi) : \sigma(L) = L\}$$

of all isometries from $L$ on itself.

2.4 Hermitian lattices over number fields

Let $K$ be a number field with maximal order $\mathfrak{O}$. Further, let $(V, \Phi)$ be a hermitian space over $E$ and fix some maximal order $\mathcal{O}$ in $E$.

For the remainder of this work, some more notation will be needed.

1. The space $(V, \Phi)$ is called (totally positive) definite, if $K$ is totally real and $Q_\Phi(x)$ is totally positive for all nonzero $x \in V$.

2. The set of all places of $K$ will be denoted by $\Omega(K)$. For $v \in \Omega(K)$, let $K_v$ be the completion of $K$ at $v$. Similarly $V_v := V \otimes_K K_v$ is the completion of $V$ at $v$. By linearity, the form $\Phi$ extends to $V_v$. Hence $(V_v, \Phi)$ is a hermitian space over $E_v := E \otimes_K K_v$. 

19
3. The set of all prime ideals of \( \mathfrak{o} \) will be denoted by \( \mathbb{P}(\mathfrak{o}) \). The prime ideals are identified with the finite places of \( K \). Hence it makes sense to write \( \mathbb{P}(\mathfrak{o}) \subset \Omega(K) \). Further, for \( p \in \mathbb{P}(\mathfrak{o}) \) let \( \text{ord}_p : K_p \to \mathbb{Z} \cup \{ \infty \} \) be the usual \( p \)-adic valuation.

4. Let \( p \in \mathbb{P}(\mathfrak{o}) \). The completion of \( \mathfrak{o} \) at \( p \) will be denoted by \( \mathfrak{o}_p \). Moreover, if \( M \) is an \( \mathfrak{o} \)-module, then \( M_p := M \otimes_{\mathfrak{o}} \mathfrak{o}_p \) is the completion of \( M \) at \( p \). In particular, given an \( \mathcal{O} \)-lattice \( L \) in \( (V, \Phi) \), then \( L_p \) is an \( \mathcal{O}_p \)-lattice in \( (V_p, \Phi) \).

5. Let \( K_{>0} = \{ a \in K^* ; \sigma(a) > 0 \text{ for all real embeddings } \sigma : K \to \mathbb{R} \} \) be the subset of totally positive elements. Further, let \( \mathfrak{o}_{>0} := K_{>0} \cap \mathfrak{o} \).

6. The free abelian group of all fractional ideals of \( \mathfrak{o} \) will be denoted by \( \mathcal{I}(\mathfrak{o}) \) and

\[
\text{Cl}(K) := \text{Cl}(\mathfrak{o}) := \mathcal{I}(\mathfrak{o})/\{ a\mathfrak{o} ; a \in K^* \}
\]

\[
\text{Cl}^+(K) := \text{Cl}^+(\mathfrak{o}) := \mathcal{I}(\mathfrak{o})/\{ a\mathfrak{o} ; a \in K_{>0} \}
\]

denote the class group and narrow class group of \( K \) (or \( \mathfrak{o} \)) respectively.

7. The group of roots of unity in a number field \( F \) will be denoted by \( \mu(F) \).

**Theorem 2.4.1 (Local-Global Principle)** Two hermitian spaces \( (V, \Phi) \) and \( (V', \Phi') \) over \( E \) are isometric, if and only if their completions \( (V_v, \Phi) \) and \( (V'_v, \Phi') \) are isometric at every place \( v \in \Omega(K) \).

**Proof.** The problem was solved by H. Minkowski, H. Hasse, W. Landherr, M. Kneser and T. Springer. For a proof, see for example [Sch85, Chapter 10]. \( \square \)

In particular, the classification of hermitian spaces over \( E \) follows immediately from the classification of hermitian spaces over \( \mathbb{R}, \mathbb{C} \) and non-Archimedean local fields. The latter classification will be discussed in Chapter 3 while the first two cases are handled by Proposition 2.1.5. For \( \mathcal{O} \)-lattices, the Local-Global Principle does not hold in general. This leads to the following definition.

**Definition 2.4.2** Let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). The class and genus of \( L \) are

\[
\text{cls}(L) := \{ L' \subset V ; L' \text{ is an } \mathcal{O} \text{-lattice isometric to } L \},
\]

\[
\text{gen}(L) := \{ L' \subset V ; L' \text{ is an } \mathcal{O} \text{-lattice such that } L_p \cong L'_p \text{ for all } p \in \mathbb{P}(\mathfrak{o}) \}.
\]

So it makes sense to say that the Local-Global Principle holds for some \( \mathcal{O} \)-lattice \( L \) in \( (V, \Phi) \) if and only if \( \text{gen}(L) = \text{cls}(L) \). In the indefinite case, one can usually tell a priori for which lattices the Local-Global Principle holds, see Chapter 5 for details. If \( (V, \Phi) \) is definite, such a classification is much more difficult and it is actually the goal of this work. First, an algorithm to compute isometries will be given. This allows to decide if any \( \mathcal{O} \)-lattice \( L' \) lies in the same class as \( L \).
Lemma 2.4.3 Let \( L \) and \( L' \) be \( \mathcal{O} \)-lattices in \((V, \Phi)\). Further, let the \( \mathbb{Q} \)-algebra \( E \) be generated by the subset \( \mathcal{B} \subset E \). Given \( \alpha \in E \), the map

\[
F_\alpha : V \times V \to \mathbb{Q}, \quad (x, y) \mapsto T_{K/Q}(T(\alpha \Phi(x, y))).
\]

defines a rational bilinear form on the \( \mathbb{Q} \)-vector space \( V \). For any \( \mathbb{Q} \)-linear map \( \sigma : V \to V \), the following statements are equivalent:

1. \( \sigma \) is an isometry of the \( \mathcal{O} \)-lattices \( L \) and \( L' \).
2. \( \sigma(L) = L' \) and \( F_\alpha(\sigma(x), \sigma(y)) = F_\alpha(x, y) \) for all \( x, y \in V \) and all \( \alpha \in \mathcal{B} \cup \{1\} \).

Proof. Clearly, 1. implies 2. Suppose now 2. holds and let \( T_{E/K} := T_{K/Q} \circ T \) denote the reduced trace of the \( \mathbb{Q} \)-algebra \( E \). Since the algebra \( E \) is separable over \( \mathbb{Q} \), the bilinear form \( E \times E \to \mathbb{Q}, \quad (\alpha, \beta) \mapsto T_{E/Q}(\alpha \beta) \) associated to \( T_{E/Q} \) is non-degenerate, see [Rei03, Section 7c] for details. In particular, \( F_1 \) is non-degenerate. For \( \alpha \in \mathcal{B} \) and \( x, y \in V \) it follows that

\[
F_1(\sigma(x), \sigma(y)) = F_1(\alpha x, \alpha y) = F_\alpha(x, y) = F_\alpha(\sigma(x), \sigma(y)) = F_1(\alpha \sigma(x), \sigma(y)).
\]

Hence \( \sigma(\alpha x) = \alpha \sigma(x) \). But then \( \sigma \) is \( E \)-linear, since \( \mathcal{B} \) generates \( E \) as a \( \mathbb{Q} \)-algebra. Thus

\[
T_{E/Q}(\alpha \Phi(x, y)) = F_\alpha(x, y) = F_\alpha(\sigma(x), \sigma(y)) = T_{E/Q}(\alpha \Phi(\sigma(x), \sigma(y)))
\]

for all \( x, y \in V \) and all \( \alpha \in E \). Since the bilinear form of \( T_{E/Q} \) is non-degenerate, it follows that \( \sigma \in U(V, \Phi) \).

\[\square\]

Remark 2.4.4 Suppose \((V, \Phi)\) is definite. Then:

1. The form \( F_1 \) of Lemma 2.4.3 is positive definite. Hence the number of isometries between two \( \mathcal{O} \)-lattices in \((V, \Phi)\) is finite.
2. In [PS97], W. Plesken and B. Souvignier present an algorithm to compute all isometries between two \( \mathbb{Z} \)-lattices preserving several rational bilinear forms, provided at least one of the forms is positive definite. Hence one can compute isometries and automorphism groups of \( \mathcal{O} \)-lattices in \((V, \Phi)\) using this algorithm and Lemma 2.4.3.
3. Let \( L \) be an \( \mathcal{O} \)-lattice in \( V \). If \( E \) is commutative, then

\[
\mu(E) \to \text{Aut}(L), \quad \varepsilon \mapsto (v \mapsto \varepsilon v)
\]

is a monomorphism. Hence \( \# \mu(E) \) divides \( \# \text{Aut}(L) \).

Theorem 2.4.5 Let \( L \) be an \( \mathcal{O} \)-lattice in \((V, \Phi)\). Then there exist finitely many lattices \( L_1, \ldots, L_h \in \text{gen}(L) \) such that \( \text{gen}(L) = \bigcup_{i=1}^h \text{cls}(L_i) \). The number \( h \) is called the class number of \( \text{gen}(L) \) (or \( L \)) and will be denoted by \( h(\text{gen}(L)) \) or \( h(L) \).
Proof. The theorem is a special case of a much more general result of A. Borel on algebraic groups [Bor63, Theorem 5.1]. Alternatively, it can also be deduced as follows. The assertion is true for indefinite spaces due to strong approximation, for details see Chapter 5. For definite spaces, the sum \( \sum_{M \in \text{gen}(L)} \frac{1}{\# \text{Aut}(M)} \) is a rational number by Siegel's Mass formula, c.f. Theorem 4.2.3. Further, the previous result shows that \( \text{Aut}(M) \) can be viewed as a finite subgroup of \( \text{GL}_{mn}(\mathbb{Q}) \) and thus its order is bounded from above by some constant depending only of \( nm \) by a result of H. Minkowski [Min87]. Hence the class number is finite. \qed

Remark 2.4.6 Two genera \( G \) and \( G' \) of hermitian \( \mathcal{O} \)-lattices are said to be similar, if \( G' = \{ L^a ; L \in G \} \) for some \( a \in \mathbb{K}^* \). Since similar genera necessarily share the same class number, the classification of all genera with a given class number reduces to the enumeration of all similarity classes of such genera. This will turn out to be a finite problem, provided that the rank of the lattices it not tiny, see Chapter 6 for details.

The concept of definite indecomposable lattices was introduced by M. Kneser for quadratic lattices over \( \mathbb{Z} \). It readily generalizes to definite \( \mathcal{O} \)-lattices in \( (V, \Phi) \). This is the last goal for this section.

Definition 2.4.7 Let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). The lattice \( L \) is said to be indecomposable, if it cannot be written as an orthogonal sum \( L = L_1 \perp L_2 \) with \( L_1 \neq \{ 0 \} \). A vector \( v \in L \) is called indecomposable, if \( v \) cannot be written in the form \( v = v_1 + v_2 \) with \( v_i \in L - \{ 0 \} \) and \( \Phi(v_1, v_2) = 0 \).

Lemma 2.4.8 Let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). If \( (V, \Phi) \) is definite, then every \( x \in L \) is a sum of indecomposable vectors.

Proof. Without loss of generality, \( L \) is integral. If \( x \) is indecomposable, there is nothing to show. If \( x \) is decomposable, then \( x = x_1 + x_2 \) with \( x_i \in L - \{ 0 \} \) and \( \Phi(x_1, x_2) = 0 \). In particular, \( 0 < T_{K/\mathbb{Q}}(\Phi(x_i)) < T_{K/\mathbb{Q}}(\Phi(x)) \). The result follows by induction. \qed

Theorem 2.4.9 Let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). If \( (V, \Phi) \) is definite, then \( L \) admits a unique orthogonal decomposition \( L = \bigoplus_{i=1}^r L_i \) into indecomposable lattices \( L_1, \ldots, L_r \).

Proof. The proof follows [Kne02, Satz (27.2)]. Let \( L = \bigoplus_{i=1}^r L_i' \) be any orthogonal decomposition. If \( x \in L \) is indecomposable, then \( x \in L_i' \) for some \( i \). Thus two indecomposable elements \( x, y \in L \) are said to be equivalent if and only if there exists some indecomposable elements \( x = x_1, \ldots, x_r = y \in L \) such that \( \Phi(x_i, x_{i+1}) \neq 0 \) for all \( 1 \leq i < r \). This defines an equivalence relation on the set of indecomposable elements of \( L \). Since the equivalence classes give rise to an orthogonal decomposition of \( (V, \Phi) \) there are at most \( m := \text{dim}_E(V) \) such classes \( K_1, \ldots, K_k \) say. Denote by \( L_i \) the \( \mathcal{O} \)-submodule of \( L \) generated by \( K_i \). Then \( L = \bigoplus_{i=1}^k L_i \) since each vector in \( L \) is a sum of indecomposable ones. Moreover, each component \( L_i \) is indecomposable and contained
in $L'_j$ for some $j$.

To prove the uniqueness, assume that all $L'_j$ are also indecomposable. For $1 \leq j \leq \ell$ let $I_j = \{1 \leq i \leq k \mid L_i \subseteq L'_j\}$ and set $M_j := \oplus_{i \in I_j} L_i \subseteq L'_j$. It suffices to show that $L'_j = M_j$ for all $j$ since then $|I_j| = 1$. Let $x \in L'_j$. Write $x = \sum_{i=1}^{|I_j|} x_i$ with $x_i \in M_i \subseteq L'_i$ for all $i$. Since $\oplus_{i=1}^\ell L'_i = L$ this implies $x_i = 0$ for all $i \neq j$. So $M_j = L'_j$ as claimed. \qed
3 Hermitian lattices over complete discrete valuation rings

The aim of this chapter is to give a brief overview on the classification of hermitian forms over complete discrete valuation rings.

Unless stated otherwise, the field $K$ will be complete with respect to a surjective, discrete valuation $\text{ord}: K \to \mathbb{Z} \cup \{\infty\}$. Let $\mathfrak{o} = \{a \in K; \text{ord}(a) \geq 0\}$ be the corresponding valuation ring and let $\mathfrak{p} = \mathfrak{p}_o = \{a \in K; \text{ord}(a) > 0\}$ be the maximal ideal of $\mathfrak{o}$. Further, the residue class field $\mathfrak{o}/\mathfrak{p}$ is always assumed to be finite.

3.1 Local fields

Let $q$ be the order of the residue class field $\mathfrak{o}/\mathfrak{p}$. The order of the quotient group $\mathfrak{o}/(\mathfrak{o}^*)^2$ equals $2q^{\text{ord}(2)}$, see [O’M73, 63:9] for details. In particular, if $K$ is non-dyadic, i.e. $2 \in \mathfrak{o}^*$, then $\mathfrak{o}/(\mathfrak{o}^*)^2$ is isomorphic to $C_2$. If $K$ is dyadic however, the quotient $\mathfrak{o}^*/(\mathfrak{o}^*)^2$ is much larger. In this case an additional invariant, the so called quadratic defect, will be needed for the classification of hermitian lattices. However, there is no need to make a general assumption on the characteristic of $\mathfrak{o}/\mathfrak{p}$ right now since most of the results in this section hold whether $K$ is dyadic or not.

**Definition 3.1.1** Let $a \in K$. The quadratic defect $\mathcal{d}(a)$ of $a$ is

$$\mathcal{d}(a) := \bigcap_{b \in K} (a - b^2)\mathfrak{o}.$$ 

**Lemma 3.1.2** Let $a, b \in K$.

1. Then $\mathcal{d}(ab^2) = b^2\mathcal{d}(a)$ and $\mathcal{d}(a) = (0)$ if and only if $a$ is a square.
2. If $a \in \mathfrak{o}$, then $\mathcal{d}(a)$ is the smallest ideal $\mathfrak{a}$ of $\mathfrak{o}$ such that $a$ is a square modulo $\mathfrak{a}$.
3. If $\text{ord}(a)$ is odd or $\infty$, then $\mathcal{d}(a) = a\mathfrak{o}$. The converse is true for dyadic fields $K$.
4. If $a \in \mathfrak{o}^*$, then $\mathcal{d}(a)$ is one of the ideals

$$(0) \subsetneq 4\mathfrak{o} \subsetneq 4\mathfrak{p}^{-1} \subsetneq 4\mathfrak{p}^{-3} \cdots \subsetneq \mathfrak{p}^3 \subsetneq \mathfrak{p}.$$ 

Conversely, every such ideal is the quadratic defect of some element in $\mathfrak{o}^*$. More precisely, if $1 \leq v < \text{ord}(4)$ is odd and $u \in \mathfrak{o}^*$, then $\mathcal{d}(1 + p^vu) = p^v$. The existence of a unit of quadratic defect $4\mathfrak{o}$ follows from Theorem 3.1.7 and the fact that $K$ admits an unramified quadratic field extension.
Proof. A proof of these assertions is given in [O’M73, Section 63]. □

Quadratic defects can be computed efficiently using the following lifting argument.

Algorithm 3.1.3 QuadraticDefect(a)
Input: Some element $a \in K$.
Output: The quadratic defect $d(a)$.
1: if $\text{ord}(a)$ is odd or $\infty$ then return $a^0$.
2: if $\text{ord}(a) \neq 0$ then return $a \cdot \text{QuadraticDefect}(a/p^\text{ord}(a))$.
3: if $\text{ord}(2) = 0$ then return $(0)$ if $a$ is a square mod $p$ and return $a$ otherwise.
4: Compute $s \in \sigma^*$ such that $s^2a \equiv 1 \pmod{p}$. Replace $a$ by $as^2$.
5: Set $v = \text{ord}(a) - 1 \geq 1$.
6: while $v < \text{ord}(4)$ and $v$ is even do
7: Compute $s \in \sigma^*$ such that $s^2 \equiv (a - 1)/p^v \pmod{p}$.
8: Replace $a$ by $a/(1 + sp^v/2)^2$ and set $v = \text{ord}(a - 1)$.
9: end while
10: if $v < \text{ord}(4)$ is odd then
11: return $p^v$.
12: else if $v = \text{ord}(4)$ and $X^2 + X + (a - 1)/4 \in (\sigma/p)[X]$ is irreducible then
13: return $4\sigma$.
14: else
15: return $(0)$.
16: end if

Proof. By Lemma 3.1.2, the first three steps are correct. So one may suppose that $K$ is dyadic and $a \in \sigma^*$. Lines 6–9 replace $a$ with some element in the same square class (which does not affect the quadratic defect) such that $\text{ord}(a - 1)$ gets larger in each iteration. In particular, the algorithm terminates. By Hensel’s Lemma, $d(a) = (0)$ whenever $v > \text{ord}(4)$ and Lemma 3.1.2 shows that $d(a) = p^v$ whenever $v < \text{ord}(4)$ is odd. This leaves only the case $a = 1 - 4\delta$ with $\delta \in \sigma^*$. Again, the previous Lemma shows that $d(a) = 4\sigma$ or $a$ is a square. By Hensel’s Lemma, the latter condition holds if and only if $(1 - 4\delta) \equiv (1 + 2x)^2 \pmod{4p}$ has a solution $x \in \sigma$. But this is equivalent to $X^2 + X + \delta \in (\sigma/p)[X]$ being reducible. □

Remark 3.1.4 The proof of Algorithm 3.1.3 shows the following.

1. Let $a \in \sigma^*$. Then there exists some $u \in \sigma^*$ such that $u^2a = 1 + d$ for some $d \in \sigma$ with $d\sigma = \sigma(x)$.
2. Let $\Delta = 1 + 4\sigma \in \sigma^*$ such that $\sigma(\Delta) = \sigma\sigma = 4\sigma$. Let $f(X) = X^2 + uX + u^2\sigma \in \sigma[X]$ with $u \in \sigma^*$. Then the image of $f$ under the canonical epimorphism $\sigma[X] \to (\sigma/p)[X]$ is irreducible. By Hensel’s Lemma, $f$ itself must be irreducible.

Lemma 3.1.5 Let $F$ be a field such that

- $F$ is finite or
Then \( F = \{ x^2 + y^2 ; x, y \in F \} \).

**Proof.** By Hensel’s Lemma, one may assume that \( q := |F| \) is finite. The case that \( q \) is even is trivial. Suppose now that \( q \) is odd. If \( F^2 \), the set of squares in \( F \), is closed under addition, it would be a subgroup of \( (F,+). \) But this is impossible, since \( \# F^2 = \frac{q+1}{2} \) does not divide \( q \). \( \square \)

**Definition 3.1.6** For non-zero elements \( a,b \) in a local field \( F \), the Hilbert symbol is defined as

\[
(a,b) := \begin{cases} +1 & \text{if } ax^2 + by^2 = z^2 \text{ has a non-zero solution } (x,y,z) \in F^3, \\ -1 & \text{otherwise.} \end{cases}
\]

So \( (a,b) = +1 \) if and only if the quadratic form \( \langle a,b \rangle \) represents \( 1 \). Hence \( (a,b) = +1 \) for all \( a,b \in C \). Similarly, if \( F = \mathbb{R} \), then \( (a,b) = -1 \) if and only if \( a,b \) are both negative.

**Theorem 3.1.7** Let \( \Delta \in o^* \) be an element of quadratic defect \( 4o \).

1. \( (a, \Delta) = (-1)^{\ord(a)} \) for all \( a \in K^* \).
2. If \( K \) is non-dyadic and \( a,b \in K \) such that \( \ord(a) \equiv \ord(b) \equiv 0 \mod 2 \), then \( (a,b) = +1 \).
3. The Hilbert symbol is a symmetric, non-degenerate bilinear form on the \( \mathbb{F}_2 \)-vector space \( K^*/(K^*)^2 \). Non-degenerate means that if \( a \in K^* - (K^*)^2 \) then \( (a,b) = -1 \) for some \( b \in K^* \).
4. If \( E \cong K[x]/(x^2 - a) \) for some \( a \in K^* \), then \( b \in N(E^*) \) if and only if \( (a,b) = 1 \).
   
   In particular, \( K^*/N(E^*) \cong \begin{cases} C_1 & \text{if } a \in (K^*)^2, \\ C_2 & \text{if } a \notin (K^*)^2. \end{cases} \)
5. The field \( E = K(\sqrt{\Delta}) \) is the unique unramified quadratic extension of \( K \) and \( N(E^*) = \{ a \in K^* ; \ord(a) \in 2\mathbb{Z} \} \). In particular, \( \{ a \in o^* ; \mathfrak{o}(a) = 4o \} = \Delta(o^*)^2 \).

**Proof.** For a proof the first assertion, see [O’M73, 63.11a]. For the second, one may assume that \( a,b \in o^* \). Moreover, there is nothing to show if \( a \) or \( b \) is a square. So without loss of generality \( a = b \). But then \( \langle a,b \rangle \) represents \( 1 \) by Lemma 3.1.5.

3. The Hilbert symbol is certainly symmetric and depends only on the square classes of \( a \) and \( b \). The linearity follows from the characterization in 4. using relative norms. The proof on the non-degeneracy is more involved. By 1. one may assume that \( a \in o^* \). Without loss of generality, \( \Delta \equiv 1 \mod 4o \) and \( a = 1 + c \) such that \( co = \mathfrak{o}(a) \). Again by 1., the case \( co \subseteq 4o \) is trivial. So only the case that \( K \) is dyadic and \( \ord(c) \) is odd remains. Let \( b := \Delta - a \). Then \( \langle a,b \rangle \cong \langle \Delta, \Delta ab \rangle \) shows that

\[
(a,b) = (\Delta, \Delta ab) = (-1)^{\ord(\Delta ab)} = (-1)^{\ord(b)} = (-1)^{\ord(c)} = -1.
\]
The fourth assertion is now clear. Further, \( E = K(\sqrt{a}) \) is unramified over \( K \) if and only if \( N(E^*) = \{ a \in K^* : \text{ord}(a) \in 2\mathbb{Z} \} \). By 1. and 3. the latter condition is equivalent to \( a \in \Delta(K^*)^2 \). This proves the last part. \( \square \)

**Theorem 3.1.8** Let \( E = \left( \frac{a,b}{F} \right) \) be a quaternion algebra over some local field \( F \) of characteristic 0 and let \( E^0 := \{ \alpha \in E : \text{tr}_{E/F}(\alpha) = 0 \} \) be its trace zero subspace.

1. The following statements are equivalent:
   a) \( E \) is a skewfield.
   b) The quaternary quadratic space \((E, nr_{E/F})\) over \( F \) is anisotropic.
   c) The ternary quadratic space \((E^0, nr_{E/F})\) over \( F \) is anisotropic.
   d) \((a,b) = -1\).

2. If \( F = \mathbb{R} \), then \( E \) is a skewfield if and only if \( a,b < 0 \). If this is the case, then \( E \cong \left( \frac{-1, -1}{R} \right) \).

3. If \( F = K \), then the quadratic space \((E, nr_{E/K})\) is universal, i.e. \( nr_{E/K}(E^*) = K^* \). Moreover, \( E \) is a skewfield if and only if \( E \cong \left( \frac{\Delta, p}{K} \right) \).

**Proof.** 1. The Structure Theorem of Artin-Wedderburn implies that the \( F \)-algebra \( E \) is either a skewfield or isometric to \( F^{2 \times 2} \). Hence a), b) and c) are certainly equivalent. Further, \((E^0, nr_{E/F}) \cong \langle -a, -b, ab \rangle \) is anisotropic if and only if \( \langle b, a, 1 \rangle \) is so. But the latter condition is equivalent to \( (a,b) = -1 \).

2. The first assertion shows that \( E = \left( \frac{a,b}{F} \right) \) is a skewfield if and only if \( a,b < 0 \). If this is the case, then \( E \cong \left( \frac{-1, -1}{R} \right) \).

3. The previous theorem and part 1d) show that \( \left( \frac{\Delta, p}{K} \right) \) is a skewfield. The fact that all quaternion skewfields over \( K \) are isometric follows from the structure of the Brauer group of \( K \), see for example [Rei03, Theorem 31.8]. Finally, if \( E \cong K^{2 \times 2} \) then clearly \( nr_{E/K}(E^*) = K^* \) and if \( E \cong \left( \frac{\Delta, p}{K} \right) \) then \( nr_{E/K}(E^*) \) contains \(-p\) as well as \( \{ x \in K^* : \text{ord}(x) \in 2\mathbb{Z} \} \). Thus \( nr_{E/K}(E^*) = K^* \) for any quaternion algebra \( E \) over \( K \). \( \square \)

Note that Hilbert symbols can be evaluated efficiently as explained in [Voi13]. Thus, given \( b \in K^* \), one can constructively decide if \( b \in N(E^*) \) as follows.

1. If \( E = K \), then \( b \in N(E^*) = (K^*)^2 \) if and only if \( \text{ord}(a) = 0 \).

2. If \( E = K[x]/(x^2 - a) \) then \( b \in N(E^*) \) if and only if \( (a,b) = 1 \).

3. If \( E \) is a quaternion algebra over \( K \), then \( b \in N(E^*) \).

28
3.2 Hermitian spaces over local fields

This section recalls the well known classification of hermitian spaces over $K$.

Definition 3.2.1 Let $(V, \Phi) \cong \langle a_1, \ldots, a_m \rangle$ be a regular quadratic space over $E = K$.

1. The Hasse invariant $c(V, \Phi) := \prod_{i<j}(a_i, a_j) \in \{\pm 1\}$ is independent of the chosen orthogonal basis.

2. The Witt invariant is defined by
   
   $$
   \omega(V, \Phi) := 
   \begin{cases} 
   c(V, \Phi) & \text{if } m \equiv 1, 2 \pmod{8}, \\
   c(V, \Phi) \cdot (-1, -\det(\Phi)) & \text{if } m \equiv 3, 4 \pmod{8}, \\
   c(V, \Phi) \cdot (-1, -1) & \text{if } m \equiv 5, 6 \pmod{8}, \\
   c(V, \Phi) \cdot (-1, \det(\Phi)) & \text{if } m \equiv 7, 0 \pmod{8}.
   \end{cases}
   $$

Theorem 3.2.2 The isometry type of any regular quadratic space $(V, \Phi)$ over $K$ is uniquely determined by its rank $m$, its determinant $d$ and its Hasse invariant $c$. Further, $(V, \Phi)$ is isotropic if and only if either

- $m = 2$ and $-d \in (K^*)^2$.
- $m = 3$ and $c = (-1, -d)$.
- $m = 4$ and $(d \notin (K^*)^2$ or $c = (-1, -1))$.
- $m \geq 5$.

Proof. See for example [O’M73, Chapter 63].

The previous result shows that there is a unique anisotropic, quaternary quadratic space over $K$ (up to isometry). By Theorem 3.1.8, this space must be a quaternion skew field over $K$ equipped with its reduced norm form and it is universal.

Theorem 3.2.3 Let $(V, \Phi)$ be a regular hermitian form over $E \neq K$ of rank $m$ and determinant $d$.

1. If $\dim_K(E) = 2$, then $(V, \Phi) \cong \langle 1, \ldots, 1, d \rangle$.
2. If $\dim_K(E) = 4$, then $(V, \Phi) \cong \langle 1, \ldots, 1 \rangle$.

In particular, the isometry type of $(V, \Phi)$ is uniquely determined by $m$ and $d \in K^*/N(E^*)$.

Proof. By Theorem 2.1.4, $(V, \Phi) \cong \langle a_1, \ldots, a_m \rangle$ for some $a_i \in K^*$. Thus the result is certainly true whenever $N(E^*) = K^*$. So only the case that $E/K$ is a quadratic field extension remains. Without loss of generality one may assume that $m = 2$. It suffices to show that $\Phi$ represents 1. This is certainly the case if $\Phi$ is isotropic. If $\Phi$ and thus $Q_\Phi$ are non-isotropic, then $\Phi$ is universal by the comment just before this theorem. So $\Phi$ represents 1 in any case.
Corollary 3.2.4 Let \((V, \Phi)\) be a regular hermitian form over \(E \neq K\) of rank \(m\) and determinant \(d\).

1. If \(\dim_K(E) = 2\), then \((V, \Phi)\) is isotropic if and only if either
   - \(m = 2\) and \(-d \in N(E^*)\) or
   - \(m \geq 3\).

2. If \(\dim_K(E) = 4\), then \((V, \Phi)\) is isotropic if and only if \(m \geq 2\).

Proof. This follows immediately from the previous theorem. \(\square\)

3.3 Jordan decompositions

Let \(\Delta = 1 - 4\rho \in \mathfrak{o}^*\) such that \(\mathfrak{d}(\Delta) = 4\rho \mathfrak{o} = 4\mathfrak{o}\). In this section, the following conventions will be used.

- If \(E/K\) is an unramified quadratic field extension, then \(E = K(\sqrt{\Delta})\).
- If \(E\) is a quaternion skewfield over \(K\), then \(E = \left(\Delta, \pi \mathfrak{o}^*\right)\).
- If \(E\) is a (skew-)field, then \(\mathcal{O}\) denotes the maximal \(\mathfrak{o}\)-order in \(E\) and \(\text{Ord}\) is the usual surjective, discrete valuation of \(E\) with valuation ring \(\mathcal{O}\).
- If \(E = K^2 \times K\), let \(\mathcal{O} = \mathfrak{o}^2 \times \mathfrak{o}^2\) and let \(\text{Ord}: E \to \mathbb{Z} \cup \{\infty\}, (a, b) \mapsto \min(\text{ord}(a), \text{ord}(b))\).
- If \(E = K^2 \times K\), let \(\mathcal{O} = \mathfrak{o}^2 \times \mathfrak{o}^2\) and let \(\text{Ord}: E \to \mathbb{Z} \cup \{\infty\}, (a, b) \mapsto \min(\text{ord}(a), \text{ord}(b), \text{ord}(c), \text{ord}(d))\).

Let \(\mathfrak{p} = \pi \mathcal{O}\) be the largest integral twosided ideal of \(\mathcal{O}\) that contains \(p \mathcal{O}\) and that is invariant under the involution \(\pi\).

- Given \(a, b \in K\), let \(A(a, b)\) denote the matrix \(\begin{pmatrix} a & 1 \\ 1 & b \end{pmatrix}\).
- For any integer \(i\), let \(H(i)\) be a binary hermitian \(\mathcal{O}\)-lattice with Gram matrix \(\begin{pmatrix} 0 & \pi^i \\ \pi^i & 0 \end{pmatrix}\). Further, for any non-negative integer \(r\), let \(H(i)^r\) denote the orthogonal sum of \(r\) copies of \(H(i)\).

Finally, \((V, \Phi)\) denotes some regular hermitian space over \(E\).
3.3 Jordan decompositions

3.3.1 The generic case

Definition 3.3.1 An orthogonal sum \( \bigoplus_{i=1}^{t} L_i \) of \( \mathcal{O} \)-lattices in \( (V, \Phi) \) is called a Jordan decomposition if the sublattices \( L_i \) are \( P_s \)-modular such that \( s_1 < s_2 < \ldots < s_t \). Two Jordan decompositions \( \bigoplus_{i=1}^{t} L_i \) and \( \bigoplus_{i=1}^{t'} L_i' \) are said to be of the same Jordan type if \( t = t' \) and for \( 1 \leq i \leq t \) the following conditions hold:

1. \( \text{rank}(L_i) = \text{rank}(L_i') \).
2. \( s(L_i) = s(L_i') \).
3. \( n(L_i) = n(L_i') \) if and only if \( n(L_i') = s(L_i) \).

The fact that every \( \mathcal{O} \)-lattice in \( (V, \Phi) \) has some Jordan decomposition follows from the following algorithm.

Algorithm 3.3.2 \textsc{JordanDecomposition}(L)
Input: An \( \mathcal{O} \)-lattice \( L \) in \( (V, \Phi) \).
Output: An orthogonal decomposition of \( L \) into modular sublattices of rank at most 2.

1. Let \( (e_1, \ldots, e_m) \) be an \( \mathcal{O} \)-basis of \( L \).
2. Set \( o := \min \{ \text{Ord}(\Phi(e_k, e_\ell)) ; 1 \leq k, \ell \leq m \} \).
3. Let \( (i, j) \in \{1, \ldots, m\}^2 \) with \( i = j \) if possible, such that \( \text{Ord}(\Phi(e_i, e_j)) = o \).
4. if \( i \neq j \) and there exists some \( \lambda \in \mathcal{O} \) such that \( \text{Ord}(T(\lambda \Phi(e_i, e_j))) = o \) then
5. Replace \( e_i \) by \( e_i + \lambda e_j \).
6. Set \( j := i \).
7. end if
8. if \( i = j \) then
9. Swap \( e_1 \) with \( e_i \).
10. for \( 2 \leq k \leq m \) do
11. Replace \( e_k \) by \( e_k - \frac{\Phi(e_k, e_1) \Phi(e_1, e_1)}{N(\Phi(e_1, e_2)) - \Phi(e_1, e_1) \Phi(e_2, e_2)} e_1 \).
12. end for
13. Set \( r := 1 \).
14. else
15. Swap \( e_1 \) with \( e_{\min(i,j)} \) and \( e_2 \) with \( e_{\max(i,j)} \).
16. for \( 3 \leq k \leq m \) do
17. Replace \( e_k \) by
\[
e_k - \frac{\Phi(e_k, e_2) \Phi(e_2, e_1) - \Phi(e_k, e_1) \Phi(e_2, e_2)}{N(\Phi(e_1, e_2)) - \Phi(e_1, e_1) \Phi(e_2, e_2)} e_1
- \frac{\Phi(e_k, e_1) \Phi(e_1, e_2) - \Phi(e_k, e_2) \Phi(e_1, e_1)}{N(\Phi(e_1, e_2)) - \Phi(e_1, e_1) \Phi(e_2, e_2)} e_2.
\]
18. end for
19. Set \( r := 2 \).
20. end if
21. return \( \sum_{i \leq r} \mathcal{O} e_i \bigoplus \text{JordanDecomposition}(\sum_{i > r} \mathcal{O} e_i) \).
3 Hermitian lattices over complete discrete valuation rings

**Theorem 3.3.3** Every $O$-lattice $L$ in $(V, \Phi)$ admits a Jordan decomposition. Further, any two Jordan decompositions of $L$ are of the same Jordan type.

**Proof.** The existence follows from Algorithm 3.3.2. For the uniqueness, note that the proof given by O’Meara in [O’M73, Theorem 91.9] for the quadratic case carries over unchanged. \hfill \square

In most cases, such an element $\lambda$ from line 4 of Algorithm 3.3.2 exists. Below are some partial results.

**Lemma 3.3.4** Let $\alpha \in E$ such that $\text{Ord}(\alpha) = o$.

1. If $E = K$ is non-dyadic, then $\text{Ord}(T(1 \cdot \alpha)) = o$.

2. If $E/K$ is an unramified quadratic field extension, then $\text{Ord}(T(\lambda \alpha)) = o$ for

$$\lambda = p^2/\alpha \cdot \begin{cases} 1 & \text{if } K \text{ is non-dyadic}, \\ \frac{1+\sqrt{\Delta}}{2} & \text{if } K \text{ is dyadic}. \end{cases}$$

3. If $E/K$ is a ramified quadratic extension, $K$ is non-dyadic and $i$ is even, then $\text{Ord}(T(\lambda \alpha)) = o$ for $\lambda = \frac{1+\sqrt{\Delta}}{2} \alpha^{-1}$.

4. If $E \cong K \times K$ or $E \cong K^{2\times2}$, then $\text{Ord}(T(\lambda \alpha)) = o$ for some idempotent $\lambda \in O$.

5. If $E$ is a quaternion skewfield and $o$ is even, then $\text{Ord}(T(\lambda \alpha)) = o$ for

$$\lambda = p^2 \cdot \begin{cases} \alpha^{-1} & \text{if } K \text{ is non-dyadic}, \\ \frac{1+\sqrt{\Delta}}{2} \alpha^{-1} & \text{if } K \text{ is dyadic}. \end{cases}$$

**Proof.** This follows from direct verifications. \hfill \square

The above result immediately yields a classification of modular lattices in almost all cases.

**Proposition 3.3.5** Let $L$ be a $\mathfrak{P}^i$-modular $O$-lattice in $(V, \Phi)$.

1. If $E = K$ is non-dyadic, then $L \cong \langle p^i, \ldots, p^i, \det(L)p^{(1-m)} \rangle$.

2. If $E \cong K \times K$ or $E \cong K^{2\times2}$ or $E/K$ is an unramified quadratic field extension then $L \cong \langle p^i, \ldots, p^i \rangle$.

3. If $E/K$ is a ramified quadratic field extension, $K$ is non-dyadic and $i$ is even, then $L \cong \langle p^{i/2}, \ldots, p^{i/2}, \det(L)p^{(1-r)/2} \rangle$.

4. If $E$ is a quaternion skewfield and $i$ is even, then $L \cong \langle p^{i/2}, \ldots, p^{i/2} \rangle$.

5. If $E/K$ is a ramified quadratic field extension, $K$ is non-dyadic and $i$ is odd, then $m$ is even and $L \cong H(i)^{m/2}$.
6. If \( E \) is a quaternion skewfield over \( K \) and \( i \) is odd, then \( m \) is even and \( L \cong H(i)^{m/2} \).

Proof. 1.–4.: From Algorithm 3.3.2 and Lemma 3.3.4 it follows that \( L \) admits an orthogonal basis. Thus 2. and 4. follow immediately from \( N(O^*) = o^* \). For the proof of 1. and 3., it suffices to show that the form \( \langle \varepsilon, \varepsilon \rangle \) represents 1 where \( \varepsilon \in o^* \) denotes some non-square. But this follows immediately from Lemma 3.1.5.

5.–6.: Since \( i \) is odd, no rank-one submodule of \( L \) has an orthogonal complement in \( L \). From Algorithm 3.3.2 it follows that \( m \) is even. So it suffices to discuss the case \( m = 2 \). After rescaling, one may also assume that \( i = 1 \). Thus \( L \) has a Gram matrix \( \left( \begin{array}{cc} a & \pi \\ \pi & b \end{array} \right) \) for some \( a, b \in p \). But then \( \det(V, \Phi) = ab - N(\pi) = -N(\pi)(1 + c) \) for some \( c \in p \). Corollary 3.2.4 shows that \( (V, \Phi) \) must be isotropic. Let \( x \) be some primitive, isotropic vector of \( L \). Then \( L \) admits some \( O \)-basis \( (x, y) \) with corresponding Gram matrix \( \left( \begin{array}{cc} 0 & \pi \\ \pi & d \end{array} \right) \) for some \( d \in p \). Let

\[
\lambda = \begin{cases} 
\frac{(1+\sqrt{\Delta})^2}{2}d\pi^{-1} & \text{if } \dim_K(E) = 4 \text{ and } K \text{ is dyadic,} \\
\frac{1}{2}d\pi^{-1} & \text{otherwise.}
\end{cases}
\]

Then \( \lambda \in O \) and the \( O \)-basis \((x, y - \lambda x)\) of \( L \) has Gram matrix \( \left( \begin{array}{cc} 0 & \pi \\ \pi & 0 \end{array} \right) \). \( \square \)

The previous result allows a classification of hermitian \( O \)-lattices in all but two cases.

**Theorem 3.3.6** Let \( (V, \Phi) \) and \( (V', \Phi') \) be hermitian spaces over \( E \). Let \( L = \bigoplus_{i=1}^t L_i \) and \( L' = \bigoplus_{i=1}^{t'} L'_i \) be Jordan decompositions of \( O \)-lattices in \( (V, \Phi) \) and \( (V', \Phi') \) respectively. Suppose that \( E \) does not satisfy any of the following two conditions.

- \( E = K \) is dyadic.
- \( E \) is a ramified quadratic field extension of the dyadic field \( K \).

Then the following statements are equivalent.

1. The lattices \( L \) and \( L' \) are isometric.

2. The lattices \( L_i \) and \( L'_i \) are isometric for all \( 1 \leq i \leq t = t' \).

3. The hermitian spaces \( (EL_i, \Phi_i) \) and \( (EL'_i, \Phi'_i) \) are isometric for all \( 1 \leq i \leq t = t' \). Here \( \Phi_i \) and \( \Phi'_i \) denote the restrictions of \( \Phi \) and \( \Phi' \) to \( EL_i \) and \( EL'_i \) respectively.

4. The hermitian spaces \( (V, \Phi) \) and \( (V', \Phi') \) are isometric, \( L \) and \( L' \) are of the same Jordan type and the following assertions hold.
   - If \( E = K \) then \( \det(L_i)/\det(L'_i) \in (o^*)^2 \) for all \( 1 \leq i \leq t \).
   - If \( E/K \) is a ramified field extension then \( \det(L_i)/\det(L'_i) \in N(O^*) \) for all \( 1 \leq i \leq t \) with \( z(L_i) \) is even.
3 Hermitian lattices over complete discrete valuation rings

Proof. Proposition 3.3.5 and the classification of hermitian spaces over local fields given in Section 3.2 show that 2., 3. and 4. are equivalent. Moreover, 2. certainly implies 1.

Suppose now 1. holds. Let \( \varphi : L \to L' \) be an isometry. By Theorem 3.3.3, isometric lattices are of the same Jordan type. Hence Proposition 3.3.5 shows that \( L \) and \( L' \) are isometric whenever \( E \neq K \) and \( E/K \) is a not a ramified quadratic field extension.

Suppose now \( E = K \) or \( E/K \) is a ramified quadratic field extension. Then \( L_1/\mathfrak{N}L_1 \) and \( L'_1/\mathfrak{N}L'_1 \) are hermitian spaces over \( O/\mathfrak{N} \) of the same rank. Let \( \tau : L' \to L'_1 \) be the canonical projection. Then

\[
L_1/\mathfrak{N}L_1 \to L'_1/\mathfrak{N}L_1, \ x + pL_1 \mapsto \tau(\varphi(x)) + pL'_1
\]

induces an isometry of hermitian spaces and thus \( \det(L_1) \equiv \det(L'_1) \mod p \). Hence \( \det(L_i) \) is an integer.

The two remaining cases are much more involved. They will be discussed in the next sections.

3.3.2 The quadratic, dyadic case

In this section, let \( E = K \) be dyadic. The classification of quadratic lattices over \( K \) is due to T. O’Meara. In this case, more invariants are needed to distinguish the isometry classes of \( \mathfrak{o} \)-lattices.

Definition 3.3.7 Let \( L \) be an \( \mathfrak{o} \)-lattice in \((V, \Phi)\) and let \( \mathfrak{a} \) be a fractional ideal of \( \mathfrak{o} \).

1. For \( a, b \in K^* \), the equivalence relation \( \equiv \) is defined as

\[
a/b \in \mathfrak{o}^* \quad \text{and} \quad \mathfrak{o}(a/b) \subseteq \mathfrak{a}/b.
\]

2. The norm group \( \mathfrak{g}(L) \) is the additive subgroup \( Q_\Phi(L) + 2s(L) \) of \((K, +)\). An element \( \alpha \in \mathfrak{g}(L) \) is called a norm generator of \( L \) if \( \alpha \mathfrak{o} = \mathfrak{n}(L) \).

3. Since \( 2s(L) \subseteq \mathfrak{g}(L) \), there exists a maximal fractional ideal \( \mathfrak{m}(L) \) contained in \( \mathfrak{g}(L) \).

Then the weight \( \mathfrak{w}(L) \) is the fractional ideal \( 2s(L) + \mathfrak{p}m(L) \).

Proposition 3.3.8 The scale, norm and weight of an \( \mathfrak{o} \)-lattice \( L \) in \((V, \Phi)\) satisfy the following conditions.

1. \( 2s(L) \subseteq \mathfrak{w}(L) \subseteq \mathfrak{g}(L) \subseteq \mathfrak{n}(L) \subseteq \mathfrak{s}(L) \).

2. \( \mathfrak{w}(L) = \mathfrak{n}(L) \) if and only if \( \mathfrak{n}(L) = 2s(L) \).

3. If \( \text{ord}(\mathfrak{n}(L)) + \text{ord}(\mathfrak{w}(L)) \) is even, then \( \mathfrak{w}(L) = 2s(L) \).

Proof. See [O’M73, Section 93].

Norm generators and weights can be computed easily using the following result.

34
Lemma 3.3.9 Let $L$ be a $\mathfrak{o}$-lattice in $(V, \Phi)$ with basis $(x_1, \ldots, x_m)$.

1. If $n(L) = 2s(L)$ let $\alpha$ be any generator of $n(L)$; otherwise let $\alpha = Q_\Phi (x_i)$ for some $1 \leq i \leq m$ that makes $\alpha \Phi$ maximal. Then $\alpha$ is a norm generator of $L$.

2. If $\alpha'$ is any norm generator of $L$, then

$$w(L) = 2s(L) + \sum_{j=1}^m \alpha' d(Q_\Phi(x_j)/\alpha') .$$

3. $\gamma \in K$ is a norm generator of $L$ if and only if $\alpha \equiv \gamma \mod w(L)$.

Proof. See [O’M73, Section 93].

Norm generators and weights are enough to distinguish isometry classes of modular lattices.

Theorem 3.3.10 Let $i \in \mathbb{Z}$. Let $L$ and $L'$ be $p^i$-modular $\mathfrak{o}$-lattices in $(V, \Phi)$ with norm generators $\alpha$ and $\alpha'$ respectively. Then the following statements are equivalent:

1. $L$ and $L'$ are isometric.
2. $L$ and $L'$ represent the same numbers, i.e. $g(L) = g(L')$.
3. $w(L) = w(L')$ and $\alpha \equiv \alpha' \mod w(L)$.

Proof. See [O’M73, Theorem 93:16 and 93:4].

Proposition 3.3.11 Let $L$ be a unimodular lattice in $(V, \Phi)$ with determinant $d \in \mathfrak{o}^*$ and weight $w(L) = p^b$. Let $\Delta = 1 - 4\varrho \in \mathfrak{o}^*$ such that $d(\Delta) = 4\varrho = 4\varrho_0$.

1. If $m = \dim_K(V) = 2r + 1$ is odd, then either $b = e$ or $b < e$ is odd.
   a) If $\omega(V, \Phi) = +1$, then
   $$L \cong \langle A(p^b, 0) \rangle \perp \langle -1 \rangle^r d \perp H(0)^{r-1} .$$
   b) If $\omega(V, \Phi) = -1$, then $b < e$ and
   $$L \cong \langle A(p^b, 4p\varrho_0 - b) \rangle \perp \langle \Delta^{-1}(-1)^r d \rangle \perp H(0)^{r-1} .$$

2. Suppose $m = \dim_K(V) = 2r$ is even. Let $\alpha$ be a norm generator of $L$ and let $\gamma \in \mathfrak{o}$ such that $\text{disc}(L) = (1 + \gamma) \cdot (\mathfrak{o}^*)^2$ and $d(1 + \gamma) = \gamma \mathfrak{o}$. Then $\gamma \in n(L)w(L)$ and $L$ is isometric to one of the following lattices.
   a) If $\text{ord}(\alpha) + b$ is even, then $b = e$ and
   $$L \cong \langle A(\alpha, -\gamma \alpha^{-1}) \rangle \perp H(0)^{r-1} . \tag{I}$$
3 Hermitian lattices over complete discrete valuation rings

\[ L \cong (A(\alpha, -\gamma \alpha^{-1})) . \] (II)

Further, either \( e = b \) or \( e > b = \text{ord}(\gamma) - \text{ord}(\alpha) \).

\( \textbf{Theorem 3.3.13 (} \text{[O'M73, Theorem 93:28]} \text{)} \)

Let \( L \) be an isometric lattice to either

\[ \langle A(\alpha, -\gamma \alpha^{-1}) \rangle \perp \langle A(p^b, 0) \rangle \perp H(0)^{r-2} \] (IIIa)

or

\[ \langle A(\alpha, -(\gamma - 4g)\alpha^{-1}) \rangle \perp \langle A(p^b, 4gp^{-b}) \rangle \perp H(0)^{r-2} . \] (IIIb)

\( \textbf{Proof.} \) This is a consequence of Theorem 3.3.10. See [O'M73, Examples 93:17–18] for details. \( \Box \)

\( \textbf{Remark 3.3.12} \) Suppose the notation of Proposition 3.3.11. Witt symbols can be used to distinguish between lattices of type (IIIa) and (IIIb). More precisely, suppose \( \dim_K(V) = 2r \geq 4 \). Then any unimodular \( \mathfrak{o} \)-lattice \( L \) in \( (V, \Phi) \) with \( \text{ord}(n(L)\mathfrak{m}(L)) \) odd is of type (IIIa) if and only if \( \omega(V, \Phi) \) equals the Hilbert symbol \( (\alpha, 1 + \gamma) \).

Let \( L = \bigoplus_{j=1}^s L_i \) be a Jordan decomposition. Let \( s_i := s(L_i) \) and \( \mathfrak{m}_i = \mathfrak{m}(L_i) \). Further pick some norm generator \( \alpha_i \) of \( L_i \). Then

\[ (t, s_1, \ldots, s_t, \alpha_1, \ldots, \alpha_t, \mathfrak{m}_1, \ldots, \mathfrak{m}_t) \]

are called the \textbf{fundamental invariants} of \( L \). Using the fundamental invariants of \( L \), one defines the ideals \( f_1, \ldots, f_{t-1} \) by

\[ f_{i} s_{i}^2 = \begin{cases} \alpha_i \alpha_{i+1} p^d \Phi & \text{if } \text{ord}(\alpha_i \alpha_{i+1}) \text{ is odd} \\ p(\alpha_i \alpha_{i+1}) + \alpha_i \mathfrak{m}_{i+1} + \alpha_{i+1} \mathfrak{m}_i + 2s_i p^{\text{ord}(\alpha_i \alpha_{i+1})/2} & \text{otherwise.} \end{cases} \]

Suppose that the lattices \( L \) and \( L' \) have the fundamental invariants \( (t, s_i, \alpha_i, \mathfrak{m}_i) \) and \( (t', s'_i, \alpha'_i, \mathfrak{m}'_i) \) respectively. The lattices \( L \) and \( L' \) are said to have the same fundamental invariants if \( t = t' \) and for all \( 1 \leq i \leq t \):

\[ s_i = s'_i, \quad \mathfrak{m}_i = \mathfrak{m}'_i \quad \text{and} \quad \alpha_i \cong \alpha'_i \mod \mathfrak{m}_i . \]

Isometric lattices have the same fundamental invariants. Conversely, T. O'Meara proved the following classification.

\( \textbf{Theorem 3.3.13 (} \text{[O'M73, Theorem 93:28]} \text{)} \) Let \( L \) and \( L' \) be lattices in \( (V, \Phi) \). Let \( L_1 \perp \ldots \perp L_t \) and \( L'_1 \perp \ldots \perp L'_t \) be Jordan decompositions of \( L \) and \( L' \) respectively. Suppose that \( L \) and \( L' \) have the same fundamental invariants \( (t, s_i, \alpha_i, \mathfrak{m}_i) \). Then \( L \) and \( L' \) are isometric if and only if the following conditions hold for all \( 1 \leq i \leq t - 1 \):

1. \( \det L_{(i)} / \det L'_{(i)} \equiv 1 \mod f_i . \)

2. The quadratic space \( KL_{(i)} \) embeds into \( KL'_{(i)} \perp \langle \alpha_{i+1} \rangle \) when \( f_i \subsetneq 4\alpha_{i+1}^{-1} \mathfrak{m}_{i+1}^{-1} . \)

3. The quadratic space \( KL_{(i)} \) embeds into \( KL'_{(i)} \perp \langle \alpha_i \rangle \) when \( f_i \subsetneq 4\alpha_i \mathfrak{m}_i^{-1} . \)

Here \( L_{(i)} = L_1 \perp \ldots \perp L_i \) and \( L'_{(i)} = L'_1 \perp \ldots \perp L'_i . \)
3.3 Jordan decompositions

3.3.3 The hermitian, ramified dyadic case

Let $E/K$ be a ramified quadratic field extension and suppose that $K$ is dyadic. Let $\pi$ be a generator of $\mathfrak{p}$. Then $p := \pi \mathfrak{p}$ is a generator of $\mathfrak{p}$.

Further, let $\mathcal{D}^{-1} := \{ \alpha \in E; T(\alpha \mathcal{O}) \subseteq \mathfrak{o} \}$ be the inverse different of $E/K$. Then $\mathcal{D} = \pi^e \mathcal{O}$ for some $e \geq 2$ and

$$T(\mathcal{D}^{-1}) = T(\pi \mathcal{D}^{-1}) = \mathfrak{o}.$$ 

Thus for any $i \in \mathbb{Z}$

$$T(\pi^i \mathcal{O}) = T(\pi^{i+e} \mathcal{D}^{-1}) = p^{\lceil \frac{i+e}{2} \rceil}.$$ 

Similar to the quadratic defect, is the concept of the normic defect.

Definition 3.3.14 The normic defect of $a \in K$ is defined by

$$d_E(a) := \bigcap_{\beta \in E} (a - N(\beta))\mathfrak{o}.$$ 

For any fractional ideal $a$ of $\mathfrak{o}$, there is an equivalence relation on $K^*$ defined by

$$a \cong b \ mod \mathfrak{a} : \iff a/b \in \mathfrak{a}^* \ and \ a - b N(\alpha) \in \mathfrak{a} \ for \ some \ \alpha \in E^*.$$ 

Remark 3.3.15 Let $a,b \in K$. Then

1. $a \in N(E)$ if and only if $d_E(a) = (0)$.
2. $d_E(a) \subseteq a\mathfrak{o}$.
3. $d_E(na) = nd_E(a)$ for all $n \in N(E)$.
4. $a = N(\alpha) + b$ for some $\alpha \in E$ and $b\mathfrak{o} = d_E(a)$.
5. If $a,b$ are non-zero, then $a \cong b \ mod \mathfrak{a}$ if and only if $a/b \in \mathfrak{a}^*$ and $d_E(a/b) \subseteq a/b$.

In view of Remark 3.3.15/3 it suffices to discuss the normic defect of elements in the non-trivial coset of $\mathfrak{a}^* / N(\mathcal{O}^*) \cong C_2$.

Lemma 3.3.16 If $a \in \mathfrak{a}^* - N(\mathcal{O}^*)$, then $d_E(a) = p^{e-1}$.

Proof. See for example [Joh68, Proposition 6.1].

Corollary 3.3.17 There exists some $u = 1 + u_0 \in \mathfrak{a}^*$ such that $d_E(u) = p^{e-1} = u_0\mathfrak{o}$ and $\mathfrak{a}^* = N(\mathcal{O}^*) \uplus u N(\mathcal{O}^*)$.

Using methods similar to [O’M73, Chapter 93], R. Jacobowitz proved the following classification.
Theorem 3.3.18 ([Jac62, Theorem 11.4]) Let \((V, \Phi)\) and \((V', \Phi')\) be two hermitian spaces over \(E\). Let \(L = \sum_{i=1}^{t} L_i \) and \(L' = \sum_{i=1}^{t} L'_i \) be Jordan decompositions of \(O\)-lattices in \((V, \Phi)\) and \((V', \Phi')\) respectively. Then \(L\) and \(L'\) are isometric if and only if the following conditions hold:

1. \(L\) and \(L'\) are of the same Jordan type.
2. \(\det(L) / \det(L') \in \mathbb{N}(O^*)\).
3. \(n_i := n(L^{g(L_i)}) = n(L'^{g(L'_i)})\) for all \(1 \leq i \leq t\).
4. \(\det(L_1 \perp \ldots \perp L_i) / \det(L'_1 \perp \ldots \perp L'_i) \cong 1 \mod \mathfrak{o} \cap n_i n_{i+1} s(L_i)^{-2}\) for all \(1 \leq i < t\).

Corollary 3.3.19 Let \(L\) and \(L'\) be \(P^i\)-modular \(O\)-lattices in \((V, \Phi)\) for some \(i \in \mathbb{Z}\). Then the following statements are equivalent:

1. \(L\) and \(L'\) are isometric.
2. \(L\) and \(L'\) represent the same numbers.
3. \(n(L) = n(L')\).

Corollary 3.3.20 Let \(L\) be a \(P^i\)-modular \(O\)-lattice in \((V, \Phi)\) and let \(m\) be the rank of \(V\) over \(E\).

1. If \(m = 2r + 1\) is odd, then \(i\) is even and
   \[ L \cong \langle u^{i/2} \rangle \perp H(i)^r \quad \text{where} \quad u N(O^*) = \text{disc}(L)p^{-mi/2} \in \mathfrak{o}^*/N(O^*). \]
   In particular, \(n(L)|O = s(L)\).
2. Suppose \(m = 2r + 2\) is even and \((V, \Phi)\) is hyperbolic. Let \(n(L) = p^k\). Then
   \[ \pi^i \mathcal{D} \subseteq p^k O \subseteq \pi^i O \quad \text{and} \quad L \cong \langle \left( \frac{p^k \pi^i}{\pi^i} \right) \rangle \perp H(i)^r \]
   Conversely, any \(O\)-lattice with such a Gram matrix is \(P^i\)-modular with norm \(p^k\).
   In particular, \(L \cong H(i)^{r+1}\) if and only if \(p^k = T(\pi^i O)\).
3. Suppose \(m = 2r + 2\) is even and \((V, \Phi)\) is not hyperbolic. Let \(n(L) = p^k\) and let \(u_0\) be as in Corollary 3.3.17. Then
   \[ \pi^i \mathcal{D} \subseteq p^k O \subseteq \pi^i O \quad \text{and} \quad L \cong \langle \left( \frac{p^k \pi^i}{\pi^i - p^k u_0} \right) \rangle \perp H(i)^r \]
   Conversely, any \(O\)-lattice with such a Gram matrix is \(P^i\)-modular with norm \(p^k\).
3.4 Construction of global hermitian spaces defined by local invariants

In this section, let $K$ be a number field. The goal of this section is the following: Given local invariants which determine a unique isometry class of hermitian spaces over $E$, compute a Gram matrix of such a space.

For any place $v \in \Omega(K)$, the Hilbert symbol of $K_v$ will be denoted by $(\cdot, \cdot)_v$. The real embeddings of $K$ will be denoted by $\sigma_1, \ldots, \sigma_r : K \to \mathbb{R}$.

Given $a, b \in K^*$, Theorem 3.1.7 shows that the set $\{v \in \Omega(K) : (a, b)_v = -1\}$ is finite. The product formula for Hilbert symbols (c.f. [O'M73, Theorem 71.18]) states that

$$\prod_{v \in \Omega(K)} (a, b)_v = 1.$$ 

In other words, the set $\{v \in \Omega(K) : (a, b)_v = -1\}$ has even cardinality.

The construction of global hermitian spaces with given local invariants can be reduced to the following important sub-problem.

**Algorithm 3.4.1**

**Input:** A finite subset $S \subset \Omega(K)$ of even cardinality and some $b \in K^*$ such that $b \notin (K_v)^2$ for all $v \in S$.

**Output:** Some $a \in \mathfrak{o}$ such that $\{v \in \Omega(K) : (a, b)_v = -1\} = S$.

1. Set $S' := \{\sigma_i \notin S ; \sigma_i(b) < 0\} \cup \{p \in \mathfrak{P}(\mathfrak{o}) - S ; p \mid 2 \text{ or } \text{ord}_p(b) \neq 0\}$.
2. Set $P := (S \cup S') \cap \mathfrak{P}(\mathfrak{o})$.
3. Let $G$ be the elementary abelian 2-group $C_2^{|S|} \times C_2^{|S'|}$ and let $\varphi : K^* \to G, a \mapsto [((a, b)_v)_{v \in S}, ((a, b)_v)_{v \in S'}]$.
4. Set $v := [(-1)_{v \in S}, (+1)_{v \in S'}] \in G$.
5. Let $\{g_1, \ldots, g_e\}$ be a set of generators of $\mathfrak{o}^*$.
6. **repeat**
7. Pick a random prime ideal $q \in \mathfrak{P}(\mathfrak{o}) - P$.
8. Let $\{g_{e+1} \mathfrak{o}, \ldots, g_{|J|} \mathfrak{o}\}$ with $g_i \in \mathfrak{o}$ generate the kernel of the homomorphism

$$\langle P \cup \{q\} \rangle \leq I(\mathfrak{o}) \to \text{Cl}(\mathfrak{o}), a \mapsto [a].$$

9. **until** $v \in \langle \varphi(g_1), \ldots, \varphi(g_f) \rangle \leq G$
10. Write $v = \prod_{j \in J} \varphi(g_j)$ for some index set $J \subseteq \{1, \ldots, f\}$.
11. **return** $a := \prod_{j \in J} g_j \in \mathfrak{o}$.

**Proof.** Provided that the algorithm terminates, its output is correct, since by construction

- $(a, b)_v = -1$ for all $v \in S$.
- $(a, b)_v = +1$ for all $v \in S' - \{q\}$.
• \((a, b)_v = +1\) for all \(v \in \Omega(K) - (S \cup S' \cup \{q\})\).

Hence \((a, b)_v\) is correct at all but possibly one place. Thus it is correct everywhere by the product formula for Hilbert symbols.

Also note that there exists some solution \(a' \in \mathfrak{o}\) by \([O'M73, \text{Theorem 71.19}]\). Let \(D\) be the divisor \(4 \prod_{p \in \mathfrak{P}} p \cdot \prod_{\sigma_i} \mathfrak{p}_i\) of \(K\). By Chebotarev's density theorem, the prime ideals of \(\mathfrak{o}\) are equally distributed over the classes of the ray class group modulo \(D\). In particular, the class of \(a' \mathfrak{o}\) is represented by some prime ideal \(q\). Conversely, any such ideal \(q\) yields a solution \(a \in \mathfrak{o}\) which is supported at \(P \cup \{q\}\). So the algorithm terminates. \(\square\)

The following remark shows that the above algorithm allows the construction of quaternion algebras with given ramification as well as hermitian spaces over \(E \neq K\) defined by local invariants.

**Remark 3.4.2**

1. Algorithm 3.4.1 requires the computation of the unit and class groups of \(\mathfrak{o}\). But other than that, it only makes use of linear algebra over \(\mathbb{F}_2\).

2. A quaternion algebra \(E = \left(\frac{a, b}{K}\right)\) is said to be **ramified** at \(v \in \Omega(K)\) if and only if \(E_v\) is a skew field. By Theorem 3.1.8, this is equivalent to \((a, b)_v = -1\). In particular, the set of all places at which \(E\) is ramified is finite, of even cardinality and contains no complex places. Conversely, let \(S \subset \Omega(K)\) be a finite subset of even cardinality which contains no complex infinite place. By weak approximation, there exists some \(b \in K^*\) such that \(b / \notin (K^*_v)^2\). Let \(a \in \mathfrak{o}\) such that \(\{v \in \Omega(K) : (a, b)_v = -1\} = S\) as computed by the Algorithm 3.4.1. Then \(\left(\frac{a, b}{K}\right)\) is ramified exactly at the places in \(S\).

Note that the set \(S\) uniquely determines the isomorphism class of \(\left(\frac{a, b}{K}\right)\) by the theorem of Hasse-Brauer-Noether-Albert, see \([Rei03, \text{Theorem 32.11}]\) for details.

3. Suppose \(E = K(\sqrt{b})\) is a quadratic field extension of \(K\). Let \((V, \Phi)\) be a regular hermitian space over \(E\) of rank \(m \geq 1\) and determinant \(d N(E^*) \in K^*/N(E^*)\). Let \(v_1, \ldots, v_s\) be the real places of \(K\) at which \(b\) is negative and let \(n_i = n(v_i, \Phi)\), c.f. Proposition 2.1.5. Loc. cit., the Local-Global Principle 2.4.1 and Theorem 3.2.3 show that

\[
(V, \Phi) \cong \langle a_1, \ldots, a_{m-1}, d \cdot \prod_{i=1}^{m-1} a_i \rangle
\]

for any \(a_1, \ldots, a_{m-1} \in K^*\) such that \(v_i(a_j) < 0 \iff j \leq n_i\). In particular, if \((V, \Phi)\) is definite, then \((V, \Phi) \cong \langle 1, \ldots, 1, d \rangle\).

By Hasse's norm theorem, \(\det(V, \Phi) = d N(E^*)\) is uniquely determined by the set

\[
S = \{v \in \Omega(K) : d \notin N(E^*_v)\}
\]

\[
= \{v \in \Omega(K) : (d, b)_v = -1\}.
\]

In particular, the set \(S\) is finite, of even cardinality and consists only of places which are non-split in \(E\). Conversely, given \(n_1, \ldots, n_r\) and \(S\), one can recover \(\det(V, \Phi)\) and thus a Gram matrix of \((V, \Phi)\) using weak approximation and Algorithm 3.4.1.
4. Suppose $E$ is a quaternion algebra with center $K$ and let $(V, \Phi)$ be a regular hermitian space over $E$ of rank $m \geq 1$. Let $v_1, \ldots, v_g$ be the real places of $K$ at which $E$ is ramified and let $n_i = n_{(V, \Phi)}$, c.f. Proposition 2.1.5. Loc. cit., the Local-Global Principle 2.4.1 and Theorem 3.2.3 show that
\[(V, \Phi) \cong (a_1, \ldots, a_m)\]
for any $a_1, \ldots, a_m \in K^*$ such that $v_i(a_j) < 0 \iff j \leq n_i$. In particular, if $(V, \Phi)$ is definite, then $(V, \Phi) \cong (1, \ldots, 1)$.

Constructing a quadratic space defined by local invariants is more difficult. The Local-Global Principle 2.4.1, Proposition 2.1.5 and Theorem 3.2.3 show that any regular quadratic space over $K$ is uniquely determined by the following invariants:

1. Its rank $m$.
2. Its determinant $d \in K^*/(K^*)^2$.
3. The finite set $\{ p \in \mathcal{P}(\mathfrak{o}) : c(V_p, \Phi) = -1 \}$.
4. The numbers $n_{(V_{x_i}, \Phi)}$ for $1 \leq i \leq r$ from Proposition 2.1.5.

Given the space $(V, \Phi)$, these invariants are easy to compute. Conversely, given these invariants, the computation of a quadratic space $(V, \Phi)$ with these invariants (provided it exists) is more involved. The algorithm given below to solve this problem is inspired by Section 6.7 of J. Cassels’ book on rational quadratic forms [Cas78].

**Algorithm 3.4.3** QUADRATICFORMFROMINVARANTS($m, d, P, (n_1, \ldots, n_r)$)

**Input:** Some integer $m \geq 1$, some nonzero element $d \in \mathfrak{o}$, some finite subset $P \subset \mathcal{P}(\mathfrak{o})$ and some integers $n_1, \ldots, n_r \in \{0, \ldots, m\}$.

**Output:** A Gram matrix of a quadratic space $(V, \Phi)$ over $K$ of rank $m$ and determinant $d$ such that $\{ p \in \mathcal{P}(\mathfrak{o}) : c(V_p, \Phi) = -1 \} = P$ and $n_{(V_{x_i}, \Phi)} = n_i$ for all $1 \leq i \leq r$.

1. Raise an error if $\text{sign}(\sigma_i(d)) \neq (-1)^{n_i}$ for some $i$.
2. Raise an error if $m = 1$ and $P \neq \emptyset$.
3. Raise an error if $m = 2$ and $-d \in (K^*_p)^2$ for some $p \in P$.
4. Raise an error if $\#\{1 \leq i \leq r ; n_i \equiv 2, 3 \pmod{4}\} + \#P$ is odd.
5. Initialise the list $D = ()$.
6. while $m \geq 2$ do
7. \hspace{1em} if $m \geq 4$ then
8. \hspace{2em} By weak approximation, compute $a \in \mathfrak{o}$ such that for all $1 \leq i \leq r$:
9. \hspace{2.5em} $\begin{cases} 
\sigma_i(a) < 0 & \text{if } n_i > 0, \\
\sigma_i(a) > 0 & \text{otherwise}.
\end{cases}$ (3.4.1)
10. \hspace{1em} else if $m = 3$ then
11. \hspace{2em} Set $P' := \{ p \in P ; (\mathfrak{o}, -d)_p = 1 \} \cup \{ p \in \mathcal{P}(\mathfrak{o}) \setminus P ; p \mid 2d \text{ and } (\mathfrak{o}, -d)_p = -1 \}$. 

41
By weak approximation, compute \( a \in \mathfrak{o} \) satisfying Eq. (3.4.1) such that
\[
\text{ord}_p(ad) \equiv 1 \pmod{2}
\]
for all \( p \in P' \).

**Proof.** The conditions imposed by lines 1–4 are both necessary and sufficient for the existence of a quadratic space with the given invariants, c.f. [O’M73, Theorems 63.23 and 72.1]. The returned answer is certainly correct if \( m = 1 \). If \( m > 1 \), the algorithm chooses some \( a \in \mathfrak{o} \) that is represented by \((V, \Phi)\) thanks to the Local-Global Principle and Theorem 3.2.2. Hence \((V, \Phi) \cong \langle a \rangle \perp (V', \Phi')\) for some quadratic space \((V', \Phi')\) of dimension \( m - 1 \). The invariants of \((V', \Phi')\) are computed in lines 15–17 from \( a \) and the corresponding invariants of \((V, \Phi)\). Hence by induction, the result is correct. \( \square \)

### 3.5 Construction of global hermitian lattices defined by local invariants

Let \( K \) be a number field and let \((V, \Phi)\) be a hermitian space over \( E \) of rank \( m \). Further, let \( \mathfrak{o} \) and \( \mathcal{O} \) be maximal orders of \( K \) and \( E \) respectively.

**Definition 3.5.1** A prime ideal \( p \) of \( \mathfrak{o} \) is called *bad*, if \( p \mid 2 \) and one of the following conditions holds:

- \( E = K \).
- \( E_p/K_p \) is a ramified quadratic field extension.

In all other cases, \( p \) is said to be *good*.

In Section 3.3, it is shown that Jordan decompositions are unique at the good but not at the bad prime ideals.

The goal of this section is to describe an algorithm which computes a representative of some genus \( G \) of \( \mathcal{O} \)-lattices in \((V, \Phi)\), which is given by local invariants. First an algorithm for computing \( \mathfrak{o} \)-maximal \( \mathcal{O} \)-lattices in \((V, \Phi)\) is presented. It is based on the following two lemmata.
3.5 Construction of global hermitian lattices defined by local invariants

Lemma 3.5.2 Let \( \mathfrak{a} \) be some fractional ideal of \( \mathcal{O} \). The set of all \( \mathfrak{a} \)-maximal \( \mathcal{O} \)-lattices in \( (V, \Phi) \) forms a single genus.

Proof. See [O’M73, Theorem 91:2] and [Shi64, Proposition 4.13]. \( \square \)

Lemma 3.5.3 Let \( M \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). Suppose that \( M_p \) is \( \mathfrak{p}_p \)-maximal for some \( p \in \mathbb{P}(\mathfrak{o}) \). Then the valuation \( v = \text{ord}_p([M^\# : M]_\mathfrak{o}) \) is given by the following local invariants.

1. Suppose \( E = K \). Let \( d \in K^* \) be a representative of the discriminant \( \text{disc}(V_p, \Phi) \) such that \( \text{ord}_p(d) \in \{0, 1\} \) and let \( e = \text{ord}_p(2) \). Then \( v \) is given by the following table.

<table>
<thead>
<tr>
<th>( m )</th>
<th>( d )</th>
<th>( \omega(V_p, \Phi) )</th>
<th>extra condition</th>
<th>( v )</th>
</tr>
</thead>
<tbody>
<tr>
<td>odd</td>
<td>–</td>
<td>+1</td>
<td></td>
<td>\text{ord}_p(d) - e(m - 1)</td>
</tr>
<tr>
<td>odd</td>
<td>–</td>
<td>–1</td>
<td></td>
<td>2 - \text{ord}_p(d) - e(m - 1)</td>
</tr>
<tr>
<td>even square</td>
<td>+1</td>
<td>–1</td>
<td></td>
<td>-em</td>
</tr>
<tr>
<td>even square</td>
<td>+1</td>
<td>–1</td>
<td></td>
<td>2 - em</td>
</tr>
<tr>
<td>even non-square</td>
<td>+1</td>
<td>( K_p(\sqrt{d})/K ) ramified</td>
<td>\text{ord}<em>p(d</em>{K(\sqrt{d})/K}) - e(m - 2)</td>
<td></td>
</tr>
<tr>
<td>even non-square</td>
<td>+1</td>
<td>( K_p(\sqrt{d})/K ) unramified</td>
<td>\text{ord}<em>p(d</em>{K(\sqrt{d})/K}) - e(m - 2)</td>
<td></td>
</tr>
<tr>
<td>even non-square</td>
<td>+1</td>
<td>( K_p(\sqrt{d})/K ) unramified</td>
<td>2 - em</td>
<td></td>
</tr>
</tbody>
</table>

2. Suppose \( E \neq K \) and \( p \) is unramified in \( E \). Then \( v = 0 \) if \( \det(V_p, \Phi) \in N(E^*) \) and \( v = 1 \) otherwise.

3. Suppose \( \text{dim}_K(E) = 2 \) and \( p \) is ramified in \( E \). Let \( e = \text{ord}_p(d_{E/K}) \). Then \( v \) is given by the following table.

<table>
<thead>
<tr>
<th>( m )</th>
<th>\text{disc}(V_p, \Phi)</th>
<th>( v )</th>
</tr>
</thead>
<tbody>
<tr>
<td>odd</td>
<td>–</td>
<td>-e(m - 1)/2</td>
</tr>
<tr>
<td>even norm</td>
<td>–</td>
<td>-em/2</td>
</tr>
<tr>
<td>even non-norm</td>
<td>–</td>
<td>1 - em/2</td>
</tr>
</tbody>
</table>

4. Suppose \( \text{dim}_K(E) = 4 \) and \( p \) is ramified in \( E \). Then \( v = -2\left\lfloor \frac{m}{2} \right\rfloor \).

Proof. This follows from a case by case discussion using the classification of \( \mathfrak{p}_p \)-maximal \( \mathcal{O}_p \)-lattices in \( (V_p, \Phi) \), c.f. for example [GHY01]. \( \square \)

Algorithm 3.5.4 LOCALMAXIMALLATTICE\((L, p, v)\)

Input: Some \( p \in \mathbb{P}(\mathfrak{o}) \) and some \( \mathcal{O} \)-lattice \( L \) in \( (V, \Phi) \) such that \( \text{ord}_p(n(L)) \geq v \).

Output: A chain of minimal \( \mathcal{O} \)-overlattices \( L_0 = L \subset L_1 \subset \cdots \subset L_r \) in \( (V, \Phi) \) such that \( (L_r)_p \) is \( \mathfrak{p}^r \)-maximal and \( (L_i)_q = L_q \) for all \( q \in \mathbb{P}(\mathfrak{o}) - \{p\} \).

1. Let \( a \in K^* \) such that \( \text{ord}_p(a) = -v \).
2. Let \( w = \text{ord}_p([M^\# : M]_\mathfrak{o}_p) \) where \( M \) denotes an \( \mathfrak{a}_p \)-maximal \( \mathcal{O}_p \)-lattice in \( (V_p, a\Phi) \), c.f. Lemma 3.5.3.
3 Hermitian lattices over complete discrete valuation rings

Let $\mathfrak{P}$ be a maximal left ideal of $\mathcal{O}$ that contains $p$.

Let $\mathcal{D}^{-1} := \{ \alpha \in E : T(\alpha \mathcal{O}) \subseteq \alpha \}$.

Initialise $i = 0$ and let $L_0$ be the lattice $L^a$ in $(V, a \Phi)$.

while $\text{ord}_p([L_i^\# : L_i]) > \omega$ do

Set $L_{i+1} := L_i + \mathcal{O}x$ for some $x \in (\mathcal{D}^{-1}L_i^\# \cap \mathfrak{P}^{-1}L_i) - L_i$ with $\text{ord}_p(Q_{a \Phi}(x)) \geq 0$.

Increment $i$.

end while

The chain $L_0^{1/a}, \ldots, L_i^{1/a}$ of $\mathcal{O}$-lattices in $(V, \Phi)$.

Proof. By construction, every lattice $L_i$ satisfies $\text{ord}_p(n(L_i)) \geq v$ and $(L_i)_q = L_q$ for all $q \neq p$. Further, $\text{ord}_p([L_i^\# : L_i])$ decreases in each step. So provided the element $x$ in line 6 always exists, the algorithm eventually returns some chain and Lemmata 3.5.2 and 3.5.3 show that the last lattice in this chain is $p^n$-maximal in $(V, \Phi)$.

To see that the element $x$ exists, suppose that $(L_i)_p$ is not $a_p$-maximal. If $p$ is non-split in $E$, then $\mathfrak{P}$ is the unique maximal left ideal of $\mathcal{O}$ over $p$. Thus the assumption on $L_i$ implies that there exists some minimal overlattice $X$ over $L_i$ which is contained in $\mathfrak{P}^{-1}L_i$ such that $\text{ord}_p(n(X)) \geq 0$. This result also holds if $p$ splits in $E$, although for different reasons. If $p$ splits in $E$, then $(L_i)_p$ has an orthogonal basis $(b_1, \ldots, b_n)$. By assumption, $a\Phi(b_i, h_i) \in \mathfrak{P}$ for some $i$. Let $\mathfrak{P}_p = \mathfrak{O}_p \pi$. Let $X$ be the $\mathcal{O}$-lattice with $X_q = L_q$ for all $q \in \mathfrak{P}(\sigma) - \{ p \}$ and $X_p = (L_i)_p + \pi^{-1}b_i$. So whether $p$ splits or not, the lattice $X$ is a minimal overlattice over $L_i$, it is contained in $\mathfrak{P}^{-1}L_i$ and $\text{ord}_p(\mathfrak{P}(X)) \geq 0$. In particular, $X$ is of the form $L_i + \mathcal{O}x$ for some $x \in \mathfrak{P}^{-1}L_i - L_i$. The condition $\text{ord}_p(n(X)) \geq 0$ readily translates into $\text{ord}_p(\mathfrak{P}_p(x, x)) \geq 0$ and $T(\mathfrak{P}_p(x, (L_i)_p)) \subseteq \mathfrak{P}_p$. The latter condition is equivalent to $x \in \mathfrak{P}_p^{-1}(L_i^\#)$. Hence in line 6, an element $x$ always exists.

Calling the above algorithm with different prime ideals yields a method for computing $a$-maximal lattices:

Algorithm 3.5.5 MaximalLattice($L, a$)

Input: Some fractional ideal $a$ of $\mathfrak{a}$ and some $\mathcal{O}$-lattice $L$ in $(V, \Phi)$ such that $n(L) \subseteq a$.

Output: An $\mathcal{O}$-lattice $M$ in $(V, \Phi)$ that is $a$-maximal and contains $L$.

1: Let $P = \{ p \in \mathfrak{P}(\sigma) \mid \text{ord}_p(a) \neq 0 \text{ or } p \mid d_{E/K} \text{ or } p \text{ is bad or } L_p \text{ is not unimodular} \}$.

2: Initialise $M = L$.

3: for $p \in P$ do

4: Replace $M$ by the last lattice returned by LocalMaximalLattice($M, p, \text{ord}_p(a)$).

5: end for

6: return $M$.

Starting from a maximal lattice, one can construct a representative of any given genus as follows.

Algorithm 3.5.6 LatticeInGenus($G$)

Input: A genus $G$ of hermitian $\mathcal{O}$-lattices in $(V, \Phi)$ given by local invariants (for example by Gram matrices) at the places in

$$P := \{ p \in \mathfrak{P}(\sigma) \mid p \mid d_{E/K} \text{ or } p \text{ is bad or } L_p \text{ is not modular for } L \in G \}.$$
Output: Some lattice $L \in G$.
1: From the given local invariants compute the norm ideal $\mathfrak{a}$ of the lattices in $G$.
2: Compute an $\mathfrak{a}$-maximal lattice $L$ in $(V, \Phi)$ using Algorithm 3.5.5.
3: for $p \in P$ do
    4: Compute an $\mathcal{O}$-sublattice $X$ of $L$ such that $X_p$ has the correct invariants at $p$ and $X_q = L_p$ for all $q \neq p$.
    5: Replace $L$ by $X$.
4: end for
5: return $L$.

Clearly, step 4 is the crucial step. Suppose $p \in P(o)$ is good. Given any Jordan decomposition of $L_p$, it is easy (c.f. Algorithm 2.2.7) to write down a random sublattice $X$ of $L$ such that

- $L_q = X_q$ for all $q \in P(o) - \{p\}$.
- The blocks of any Jordan decomposition of $X_p$ have the correct scales and ranks.

By Theorem 3.3.6, the number of local isometry classes represented by such lattices $X_p$ is at most $2^{m-1}$ and the classes are equally distributed. So one quickly finds a lattice $X$ that does the trick. At bad primes however, the task can be quite challenging since the number of isometry classes can be fairly large and they are not equally distributed. In this case, one can fall back to the following deterministic procedure which makes use of the fact that bad primes usually have small norms.

Algorithm 3.5.7 Sublattice($M, M', p,$)

Input: Some prime ideal $p$ of $o$, an $\mathcal{O}$-lattice $M'$ in a hermitian space $(V', \Phi')$ over $E$ such that $(V'_p, \Phi') \cong (V_p, \Phi)$ and an $\mathcal{O}$-lattice $M$ in $(V, \Phi)$ such that $M_p$ is $n(M'_p)$-maximal.

Output: Some $\mathcal{O}$-lattice $L \subseteq M$ such that $L_q \cong M'_q$ and $L_q = M_q$ for all $q \in P(o) - \{p\}$.

1: Let $M'_0 \subseteq \ldots \subseteq M'_r$ be the output of LOCALMAXIMALLATTICE($M', p, \ord_p(nr(M'))$).
2: Initialiase $L = M$.
3: for $i = r - 1, \ldots, 1, 0$ do
    4: repeat
        5: Compute a random maximal $\mathcal{O}$-sublattice $X$ of $L$ containing $pL$.
        6: until $X_p \cong (M'_i)_p$
    7: Replace $L$ by $X$.
8: end for
9: return $L$.

Proof. If the algorithm terminates, it certainly yields an $\mathcal{O}$-lattice $L$ with the desired properties. By induction, $(M'_{i+1})_p$ is isometric to $L_p$. Hence there exists at least one maximal $\mathcal{O}$-sublattice $X$ between $L$ and $pL$ such that $X_p \cong (M'_i)_p$. 

Note that if $(V, \Phi)$ is definite, the above search can be improved considerably. The finite group $\text{Aut}(L)$ acts on the maximal $\mathcal{O}$-subspaces of $L$ that contain $pL$. Thus one only needs to consider orbit representatives $X$ in step 5. This is extremely useful since
the local isometry classes represented by the maximal \( \mathcal{O} \)-sublattices of \( L \) are not always equally distributed at bad primes.
4 The mass formula of Siegel

In this chapter, $K$ is a totally real number field of degree $n$ with ring of integers $\mathfrak{o}$. Let $(V, \Phi)$ be a definite hermitian space over $E$ of rank $m$. If $E = K$, then $m$ is assumed to be at least 2.

Let $\mathcal{O}$ denote some fixed maximal order in $E$. Then the inverse different

$$\mathcal{D}^{-1} = \{ \alpha \in E : T(\alpha \mathcal{O}) \subseteq \mathfrak{o} \}$$

of $\mathcal{O}$ is an invertible twosided ideal of $\mathcal{O}$. Moreover, the relative discriminant ideal $d_{E/K} := N(\mathcal{D})$ does not depend on chosen maximal order $\mathcal{O}$. Note that, if $E$ is a quaternion algebra over $K$, ramified only at the prime ideals $p_1, \ldots, p_s$ of $\mathfrak{o}$, then $d_{E/K} = \prod_{i=1}^{s} p_i^2$. Hence $d_{E/K}$ is the square of the reduced discriminant as defined in [Rei03, Chapter 25].

Given an algebraic number field $F$, let $N_{F/Q} : F \to \mathbb{Q}$ be the usual norm of $F$ and the absolute value of the discriminant of $F$ will be denoted by $d_F$.

4.1 Some properties of $L$-series

In this section, some well-known results of $L$-series of number fields are recalled. For a proof of these results and more information, see for example [Neu06, Chapter VII].

Definition 4.1.1 The Dedekind zeta function $\zeta_F$ of an algebraic number field $F$ is defined by the Dirichlet series

$$\zeta_F(s) = \sum_{\mathfrak{a}} \frac{1}{N_{F/Q}(\mathfrak{a})^s}.$$ 

Here the sum ranges over all ideals $\mathfrak{a}$ of the ring of integers of $F$.

Theorem 4.1.2 Let $F$ be a number field. The series $\zeta_F(s)$ converges absolutely and uniformly on $\{ s \in \mathbb{C} : \Re(s) \geq 1 + \varepsilon \}$ for every $\varepsilon > 0$. For $\Re(s) > 1$, the series $\zeta_F(s)$ has an Euler product expansion

$$\zeta_F(s) = \prod_{\mathfrak{p}} \frac{1}{1 - N_{F/Q}(\mathfrak{p})^{-s}}$$

where $\mathfrak{p}$ ranges over the prime ideals of the ring of integers of $F$.

E. Hecke showed that $\zeta_F$ admits a meromorphic continuation on $\mathbb{C}$, with a single pole at 1 and it satisfies a functional equation relating $\zeta_F(s)$ with $\zeta_F(1 - s)$.
The mass formula of Siegel

**Theorem 4.1.3 (Hecke, Functional equation)** Let $F$ be a number field with signature $(r_1, r_2)$ and degree $n = r_1 + 2r_2$. The completed Dedekind zeta function

$$\Lambda_F(s) := \left(\frac{d_F}{4^{r_2} \pi^n}\right)^{s/2} \Gamma(s/2)\Gamma(s)\zeta_F(s) \quad (\Re(s) > 1)$$

has an analytic continuation on $\mathbb{C} \setminus \{0, 1\}$ and satisfies the functional equation

$$\Lambda_F(s) = \Lambda_F(1 - s).$$

Here $\Gamma$ denotes the usual Gamma function.

The Dedekind zeta function has a unique pole at $s = 1$ and this pole is simple. The residue $\text{Res}_1(\zeta_F)$ at $s = 1$ gives a beautiful relation between important invariants of $F$.

**Theorem 4.1.4 (Class number formula)** Let $F$ be a number field with signature $(r_1, r_2)$. The Dedekind zeta function $\zeta_F$ has an analytic continuation on $\mathbb{C} \setminus \{1\}$. It has a simple pole at $s = 1$ with residue

$$\text{Res}_1(\zeta_F) = \lim_{s \to 1} (s - 1)\zeta_F(s) = \frac{2^{r_1} (2\pi)^{r_2} \text{Reg}(F) \cdot \# \text{Cl}(F)}{\# \mu(F) \cdot d_F^{1/2}}$$

where $d_F$, $\text{Cl}(F)$, $\mu(F)$ and $\text{Reg}(F)$ denote the absolute value of the discriminant, the class group, the roots of unity and the regulator of $F$ respectively.

Let $F/K$ be a quadratic extension of the totally real number field $K$. The Galois group $\text{Gal}(F/K)$ has two irreducible characters (i.e. homomorphisms $\text{Gal}(F/K) \to \{\pm 1\}$). To each character $\chi$ of $\text{Gal}(F/K)$, one associates the so-called Artin map, which will also be denoted by $\chi$. It is the multiplicative function $\chi : I(\mathcal{O}) \to \{-1, 0, +1\}$ on the group of fractional ideals $I(\mathcal{O})$ of $\mathcal{O}$ defined by

$$\chi(p) = \begin{cases} 
0 & \text{if } \chi \neq 1 \text{ and } p \text{ ramifies in } F, \\
-1 & \text{if } \chi \neq 1 \text{ and } p \text{ is inert in } F, \\
+1 & \text{otherwise}, 
\end{cases}$$

for all prime ideals $p$ of $\mathcal{O}$. The Artin map $\chi$ gives rise to the $L$-series

$$L_K(\chi, s) = \sum_{a} \frac{\chi(a)}{N_{K/Q}(a)^s} = \prod_p \frac{1}{1 - \chi(p) N_{K/Q}(p)^{-s}} \quad (\Re(s) > 1)$$

where $a$ and $p$ range over the integral and prime ideals of $\mathcal{O}$ respectively. Clearly $L_K(1, s) = \zeta_K(s)$ for $\Re(s) > 1$.

Suppose now $\chi \neq 1$. From the decomposition of prime ideals of $\mathcal{O}$ in $F$ it follows that

$$L_K(\chi, s) = \frac{\zeta_F(s)}{\zeta_K(s)} \quad (\Re(s) > 1). \quad (4.1.1)$$

In particular, $L_K(\chi)$ has a meromorphic continuation on $\mathbb{C}$ and Theorem 4.1.3 yields a functional equation for $L_K(\chi)$ relating $L_K(\chi, s)$ with $L_K(\chi, 1 - s)$. Below, some of these identities are collected that will be used later on.
Corollary 4.1.5 Let $F$ be a quadratic field extension of the totally real number field $K$. Let $R$ be the ring of integers of $F$ and let $\chi$ be the non-trivial character of $\text{Gal}(F/K)$. Further, let $n = [K : \mathbb{Q}]$ and set $d := \frac{d_F}{d_K} = d_K \text{Nr}_{K/\mathbb{Q}}(d_F/K)$.

1. If $s \geq 2$ is an even integer, then
   \[
   \zeta_K(1-s) = \left( (-1)^{s/2} \cdot \frac{2 \cdot (s-1)!}{(2\pi)^s} \right)^n \cdot d_K^{s-1/2} \cdot \zeta_K(s).
   \]

2. If $F$ is totally real and $s \geq 2$ is an even integer, then
   \[
   \mathcal{L}_K(\chi, 1-s) = \left( (-1)^{s/2} \cdot \frac{2 \cdot (s-1)!}{(2\pi)^s} \right)^n \cdot d^{s-1/2} \cdot \mathcal{L}_K(\chi, s).
   \]

3. If $F$ is totally complex and $s \geq 1$ is an odd integer, then
   \[
   \mathcal{L}_K(\chi, 1-s) = \left( (-1)^{(s-1)/2} \cdot \frac{2 \cdot (s-1)!}{(2\pi)^s} \right)^n \cdot d^{s-1/2} \cdot \mathcal{L}_K(\chi, s).
   \]

4. If $F$ is totally complex, then
   \[
   \mathcal{L}_K(\chi, 1) = \frac{\# \text{Cl}(F)}{\# \text{Cl}(K)} \cdot \frac{(2\pi)^n}{Q \cdot \#\mu(F) \cdot d^{1/2}}
   \]
   where $Q := [R^* : \mu(F)\mathfrak{o}^*] \in \{1, 2\}$ denotes the Hasse unit index of $F/K$.

Proof. 1. This is an immediate consequence of Theorem 4.1.3. Further, 2. follows from 1. and equation (4.1.1).

3. Let $\ell := \frac{\Lambda_F(s)}{\Lambda_K(s)} = \left( \frac{d}{(4\pi)^n} \right)^{s/2} \frac{\Gamma(s)}{\Gamma(s/2)^n} \cdot \mathcal{L}_K(\chi, s) = \left( \frac{d}{(4\pi)^n} \right)^{s/2} \left( \frac{2^{s-1} (s-1)!}{\sqrt{\pi}} \right)^n \cdot \mathcal{L}_K(\chi, s).

Using the functional equation 4.1.3, one obtains
\[
\ell = \lim_{z \to 1-s} \frac{\Lambda_F(z)}{\Lambda_K(z)} = \left( \frac{d}{(4\pi)^n} \right)^{(1-s)/2} \mathcal{L}_K(\chi, 1-s) \cdot \left( \frac{1}{2} \lim_{z \to 1-s} \frac{\Gamma(z)}{\Gamma(z/2)} \cdot \frac{1 - s - z}{1 - z - \frac{s}{2}} \right)^n
\]
\[
= \left( \frac{d}{(4\pi)^n} \right)^{(1-s)/2} \mathcal{L}_K(\chi, 1-s) \cdot \left( \frac{1}{2} \frac{\text{Res}_{1-s}(\Gamma)}{\text{Res}_{1-s/2}(\Gamma)} \right)^n
\]
\[
= \left( \frac{d}{(4\pi)^n} \right)^{(1-s)/2} \mathcal{L}_K(\chi, 1-s) \cdot \left( \frac{1}{2} \cdot (-1)^{(s-1)/2} \frac{(s-1)!}{(s-1)!} \right)^n
\]

4. Follows from Theorem 4.1.4 and equation (4.1.1). \qed

Quite surprising, the values $\zeta_K(1-s)$ and $\mathcal{L}_K(\chi, 1-s)$ in the previous corollary are in fact rational numbers:
Theorem 4.1.6 (Klingen-Siegel, Shintani) Let $F/K$ be a quadratic field extension of a totally real number field $K$. Let $\chi$ be the non-trivial character of $\text{Gal}(F/K)$. Then $\zeta_K$ and $L_K(\chi)$ are rational valued at non-positive integers.

To simplify the presentation later on, the following notation will be used.

Definition 4.1.7 Suppose $d \in K^*$. If $d \notin (K^*)^2$, then $\chi_d$ denotes the non-trivial character of $\text{Gal}(K(\sqrt{d})/K)$ otherwise set $\chi_d = 1$.

4.2 Siegel’s Mass formula

Suppose $K$ is a totally real number field of degree $n$. Let $(V, \Phi)$ be a definite hermitian space over $E$ of dimension $m$.

Let $G$ be the reductive algebraic group defined by

$$G(A) = \{ \varphi \in \text{End}_A(A \otimes_K V) : \Phi(\varphi(x), \varphi(y)) = \Phi(x, y) \text{ for all } x, y \in A \otimes_K V \}$$

for every $K$-algebra $A$. The connected component of the identity will be denoted by $G^0$. The algebraic group $G$ is a form of an orthogonal, hermitian or symplectic group, depending on $\dim_K(E) = 1, 2$ or $4$. For convenience, Table 4.1 lists some invariants of $G$, which will be needed later on.

<table>

Table 4.1: Invariants of $G$

Definition 4.2.1 Let $L$ be an $O$-lattice in $(V, \Phi)$ and let $L_1, \ldots, L_h$ represent the isometry classes in $\text{gen}(L)$. Then

$$\text{Mass}(L) := \text{Mass}(\text{gen}(L)) := \sum_{i=1}^{h} \frac{1}{\# \text{Aut}(L_i)}$$

is called the mass of (the genus of) $L$.

Since the mass is invariant under scaling, it suffices to discuss the mass of integral lattices only.

Definition 4.2.2 Let $p$ be a prime ideal of $\mathfrak{o}$ of norm $q$ and let $L$ be an integral $O$-lattice in $(V, \Phi)$. Given a commutative $\mathfrak{o}$-algebra $R$, the map $\Phi$ extends to some bilinear map on $L_p \otimes_{\mathfrak{o}_p} R$. Thus $L_p$ defines a local integral group scheme $H$ via

$$H(R) = \{ \varphi \in \text{End}_{\mathfrak{o}_p \otimes R}(L_p \otimes_{\mathfrak{o}_p} R) : \Phi(x, y) = \Phi(\varphi(x), \varphi(y)) \text{ for all } x, y \in L_p \otimes_{\mathfrak{o}_p} R \}$$
for every commutative \( \mathfrak{o} \)-algebra \( R \). The local density of \( L \) at \( p \) is defined by

\[
\beta(L_p) := \frac{1}{[G : G^0]} \cdot \lim_{N \to \infty} \frac{\#H(\mathfrak{o}_p/p^N)}{q^{N \dim(G)}}.
\]

The above limit \( \beta(L_p) \) is known to stabilize for some \( N \), see for example [Sie35, Satz 2] for the case \( E = K \). However, if \( H \) is not smooth over \( \mathfrak{o} \), it does not have to stabilize at \( N = 1 \).

**Theorem 4.2.3 (Siegel)** Let \( L \) be an integral \( \mathcal{O} \)-lattice in \( (V, \Phi) \). Then \( \text{Mass}(L) \) equals

\[
(\mu/\gamma_m)^n \cdot \tau(G) \cdot d_K^{\dim(G)/2} \cdot \text{Nr}_{K/Q}(d_{E/K})^{m(m+1)/4} \cdot [L^\# : L^m(V)/2] \cdot \prod_p \beta(L_p)^{-1}
\]

where the product runs over all prime ideals of \( \mathfrak{o} \) and

\[
\tau(G) = \begin{cases} 
2 & \text{if } \dim_K(E) = 2, \\
1 & \text{otherwise},
\end{cases}
\]

is the Tamagawa number of \( G \).

\[
m(V) = \begin{cases} 
m + 1 & \text{if } E = K, \\
m & \text{if } \dim_K(E) = 2, \\
m - 1/2 & \text{if } \dim_K(E) = 4.
\end{cases}
\]

\[
\mu = \begin{cases} 
2^n & \text{if } E = K \text{ and } m \text{ is even}, \\
2^{(m+1)/2} & \text{if } E = K \text{ and } m \text{ is odd}, \\
1 & \text{otherwise}.
\end{cases}
\]

\[
\gamma_m = \prod_{i=1}^r \frac{(2\pi)^{d_i}}{(d_i - 1)!}
\]

where \( d_1, \ldots, d_r \) are the degrees of \( G \).

**Proof.** The proof in the quadratic case is due to Siegel [Sie35, Sie37]. For a proof of the general case, see [GY00, Section 10]. \( \square \)

The local factors \( \beta(L_p) \) are known in many cases. For example

- if \( E = K \) and \( 2 \notin p \) by work of C.-L. Siegel [Sie35, Sie37] and H. Pfeuffer [Pfe71a].
- if \( E = K = \mathbb{Q} \) and \( p = 2\mathbb{Z} \) by work of G. L. Watson [Wat76].
- if \( L_p \) is maximal by work of G. Shimura [Shi97, Shi99a, Shi99b], see also [GHY01].
- if \( p \) is good by work of W. T. Gan & J.-K. Yu [GY00].
- if \( p \) is bad and \( K_p/Q_2 \) is unramified by work of S. Cho [Cho].

Suppose \( p \) is good and let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). Then Gan and Yu associate to \( L_p \) several group schemes as follows. Let

\[
L_p = L_1 \perp \ldots \perp L_t
\]
be a Jordan decomposition of $L_p$, which is essentially unique by Theorem 3.3.6. Let $\mathfrak{P}$ be the largest twosided $\mathcal{O}$-ideal over $p$ that is invariant under the involution $-$ and let $s_i \in \mathbb{Z}$ such that $\mathfrak{p}(L_i) = \mathfrak{P}^{s_i}$. Further, let $\pi \in \mathfrak{P}$ such that $\mathfrak{P}_p = \pi \mathcal{O}_p$. For $1 \leq i \leq t$, the rescaled Gram matrix $\pi^{-s_i} G(L_i) \pmod{\mathfrak{P}}$ defines a (skew-)hermitian form on $L_i/\mathfrak{P}L_i$ and hence a group scheme $G_i$ over $\mathfrak{o}/p$. The local factor $\beta(L_p)$ can now be expressed in terms of these schemes:

**Theorem 4.2.4** In the above situation, let $m_i = \text{rank}(L_i)$ and $m'_i = \sum_{j > i} m_j$. If $p$ is a good prime ideal of $\mathfrak{o}$ of norm $q = \text{Nr}_{K/\mathbb{Q}}(p)$, then

$$
\beta(L_p) = [G : G^0]^{-1} \cdot q^N \cdot \prod_{i=1}^t q^{-\text{dim}(G_i)} \#G_i(\mathfrak{o}/p).
$$

Here $N = \sum_{i=1}^t d_i + ds_im_im'_i$ where $d = \text{dim}_{\mathfrak{o}/p}(\mathcal{O}/\mathfrak{P})$ and

$$
d_i = \begin{cases} tm_i^2 & \text{if } \text{dim}_K(E) = 2, p \text{ is ramified in } E \text{ and } s_i = 2t \text{ is even}, \\
 tm_i^2 + \text{dim } G_i & \text{if } \text{dim}_K(E) = 2, p \text{ is ramified in } E \text{ and } s_i = 2t + 1 \text{ is odd}, \\
 tm_i(2m_i - 1) & \text{if } \text{dim}_K(E) = 4, p \text{ is ramified in } E \text{ and } s_i = 2t \text{ is even}, \\
 tm_i(2m_i - 1) + m_i^2 & \text{if } \text{dim}_K(E) = 4, p \text{ is ramified in } E \text{ and } s_i = 2t + 1 \text{ is odd}, \\
 s_i(dm_i^2 - \text{dim } G_i) & \text{otherwise.}
\end{cases}
$$

**Proof.** See [GY00, Theorem 7.3].

For convenience, the dimension $d$, the type of $G_i$ and the cardinality of $G_i(\mathfrak{o}/p)$ are given explicitly below.

**Lemma 4.2.5** In the situation of Theorem 4.2.4, the dimension $d$ and the type of $G_i$ are given by the following table.

<table>

</tr>
</tbody>
</table>

If $\mathfrak{p}$ is bad, the computation of the local factors is much more involved. For example, [Cho] discusses the case $\mathfrak{p}$ is bad and $K_{\mathfrak{p}}/\mathbb{Q}_2$ is unramified, see also [Cho15].

Theorem 4.2.3 states Siegel’s mass formula as an infinite product of real numbers. Almost all factors are different from 1 and some are not even rational.

Both issues make the evaluation of the mass formula algorithmically difficult. These problems can be addressed by reorganizing the mass formula. For this, different local factors $\lambda(L_{\mathfrak{p}}) \in \mathbb{Q}$ have to defined such that $\lambda(L_{\mathfrak{p}}) = 1$ for all but finitely many prime ideals $\mathfrak{p}$ of $\mathfrak{o}$.

**Definition 4.2.6** Let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$ and let $\mathfrak{p}$ be a prime ideal of $\mathfrak{o}$ of norm $q$. Further, let $H_{\mathfrak{p}}$ be the quasi-split inner form of $G$ over $K_{\mathfrak{p}}$. The local factor $\lambda(L_{\mathfrak{p}})$ is defined as

$$
\lambda(L_{\mathfrak{p}}) = q^{\text{ord}_\mathfrak{p}(L_{\mathfrak{p}}:L_{\mathfrak{p}})} \cdot \frac{q^{-\dim H_{\mathfrak{p}}} \cdot \#H_{\mathfrak{p}}(\mathfrak{o}/\mathfrak{p})}{\text{disc}(\mathfrak{H}_{\mathfrak{p}})}
$$

where $\dim(V)$ is as is Theorem 4.2.3 and $a_{\mathfrak{p}}$ is determined by the following conditions:

- If $E = K$ and $m$ is even, then

$$
a_{\mathfrak{p}} = \text{ord}_\mathfrak{p}(d_{K(\sqrt{d}/K)} \cdot (1 - m)/2 + \text{ord}_\mathfrak{p}(2) \cdot m
$$

where $\text{disc}(L) = d \cdot (K^*)^2$.

- If $E = K$ and $m$ is odd then $a_{\mathfrak{p}} = \text{ord}_\mathfrak{p}(2) \cdot (m + 1)/2$.

- If $E_{\mathfrak{p}}/K_{\mathfrak{p}}$ is a ramified quadratic field extension and $m$ is even, then

$$
a_{\mathfrak{p}} = \text{ord}_\mathfrak{p}(d_{E/K}) \cdot m/2
$$

- If $E_{\mathfrak{p}}/K_{\mathfrak{p}}$ is a quaternion skew field, then $a_{\mathfrak{p}} = m(m + 1)/2$.

53
In all other cases, \( a_p = 0 \).

By [GHY01], the type of \( H_p \) is given by the following table.

<table>
<thead>
<tr>
<th>( \dim_{K}(E) )</th>
<th>( m )</th>
<th>condition</th>
<th>( H_p )</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

</tr>
</tbody>
</table>

A case by case discussion immediately yields the following version of the mass formula in terms of the \( \lambda(L_p) \).

**Proposition 4.2.7 (Siegel’s mass formula)** Let \( L \) be an \( O \)-lattice in \( (V, \Phi) \) and let \( \gamma_m \) be as in Theorem 4.2.3.

1. If \( E = K \) and \( m \) is odd, then

\[
\text{Mass}(L) = \gamma_m^{-n} \cdot d_K^{m(m-1)/4} \cdot \prod_{i=1}^{(m-1)/2} \zeta_K(2i) \cdot \prod_p \lambda(L_p) \\
= \frac{1}{2^{m(m-1)/2}} \cdot \prod_{i=1}^{(m-1)/2} |\zeta_K(1-2i)| \cdot \prod_p \lambda(L_p).
\]

2. Suppose \( E = K \) and \( m \) is even. Let \( \text{disc}(V, \Phi) = d \cdot (K^*)^2 \) and let \( \chi_d \) be as in Definition 4.1.7. Then

\[
\text{Mass}(L) = \gamma_m^{-n} \cdot d_K^{m(m-1)/4} \cdot N_{F/K}(d_{F/K})^{(m-1)/2} \prod_{i=1}^{m/2-1} \zeta_K(2i) \cdot \zeta_K(\chi_d, m/2) \cdot \prod_p \lambda(L_p)
\]

\[
= \frac{1}{2^{nm/2}} \cdot \prod_{i=1}^{m/2-1} |\zeta_K(1-2i)| \cdot |\zeta_K(\chi_d, 1-m/2)| \cdot \prod_p \lambda(L_p).
\]
3. Suppose \( \dim K(E) = 2 \). Let \( \chi \) be the non-trivial character of \( \Gal(E/K) \). Then

\[
\Mass(L) = 2^{-n} \cdot d_K^{m/2} \cdot \Nr_{K/Q}(\det_{E/K})^{m(m-1)/4} \prod_{i=1}^{m} \Omega_K(\chi^i, i) \cdot \prod_p \lambda(L_p)
\]

\[
= \frac{2}{2^{n(m-1)}} \cdot \frac{\# \Cl(E)}{\# \Cl(K) \cdot \# \mu(E) \cdot Q} \prod_{i=2}^{m} |\Omega_K(\chi^i, 1-i)| \cdot \prod_p \lambda(L_p)
\]

\[
= \frac{2}{2^{nm}} \prod_{i=1}^{m} |\Omega_K(\chi^i, 1-i)| \cdot \prod_p \lambda(L_p)
\]

where \( Q = [\mathcal{O}^*: \mu(E)^*] \in \{1, 2\} \) denotes the Hasse unit index of \( E/K \).

4. If \( \dim K(E) = 4 \), then

\[
\Mass(L) = \gamma_{m}^{-n} \cdot d_K^{m+1/2} \cdot \prod_{i=1}^{m} \zeta_K(2i) \cdot \prod_p \lambda(L_p)
\]

\[
= \frac{1}{2^{nm}} \prod_{i=1}^{m} |\zeta_K(1-2i)| \cdot \prod_p \lambda(L_p)
\]

For the remainder of this section, some properties of \( \lambda(L_p) \) are collected, that will be useful later on.

**Definition 4.2.8** For integers \( n, m, q \) such that \( 0 \leq m \leq n \), let

\[
\binom{n}{m}_q := \frac{\prod_{i=1}^{m}(1-q^i)}{\prod_{i=1}^{n}(1-q^i) \cdot \prod_{i=1}^{n-m}(1-q^i)}
\]

be the Gaussian binomial coefficient. Note that \( \binom{n}{m}_q \) is always an integer. For example if \( q \) is a prime power, then \( \binom{n}{m}_q \) is simply the number of \( m \)-dimensional subspaces of a \( n \)-dimensional vector space over \( \mathbb{F}_q \).

For good prime ideals \( p \), the factors \( \beta(L_p) \) are given by Theorem 4.2.4. Hence the computation of \( \lambda(L_p) \) at good prime ideals is straightforward. Below are some local factors that will be needed later on.

**Lemma 4.2.9** Let \( p \) be a good prime ideal of \( \mathcal{O} \) and let \( \mathfrak{P} \) be the largest twosided ideal of \( \mathcal{O} \) over \( p \) that is invariant under \(-\). Let \( L_p = L_0 \perp L_1 \) be an \( \mathcal{O} \)-lattice in \((V_p, \Phi)\) such that \( L_1 \) is \( \mathfrak{P}^i \)-modular. Write \( m_i = \text{rank}(L_i) \) and set \( q = \Nr_{K/Q}(p) \). Then \( \lambda(L_p) \) is given by the following table:
Proposition 4.2.10 Let $L$ and $M$ be $\mathcal{O}$-lattices in $(V, \Phi)$ and let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}$.

Then

1. $\lambda(L_{\mathfrak{p}}) \in \mathbb{Q}$.

2. The set $\{\mathfrak{p} \in \mathbb{P}(\mathcal{O}) : \lambda(L_{\mathfrak{p}}) \neq 1\}$ is finite.

3. $\lambda(L_{\mathfrak{p}}) = \lambda(L_{\mathfrak{p}}^c)$ for all $c \in K^*$.

4. Suppose $E \neq K$. Then $\lambda(L_{\mathfrak{p}}) \in \frac{1}{2}\mathbb{Z}$. Further, if $\lambda(L_{\mathfrak{p}}) \notin \mathbb{Z}$, then $m$ is odd and $E_{\mathfrak{p}}/K_{\mathfrak{p}}$ is a ramified quadratic field extension.

5. If $L_q = M_q$ for all $q \in \mathbb{P}(\mathcal{O}) - \{\mathfrak{p}\}$, then

\[
\text{Mass}(M) = \text{Mass}(L) \cdot \frac{\lambda(M_{\mathfrak{p}})}{\lambda(L_{\mathfrak{p}})}.
\]

Proof. The first assertion is Corollary 4.3.6, while the second follows immediately from Lemma 4.2.9. The last statement is trivial and the fourth follows from a case by case discussion using Lemma 4.2.9 and Theorems 4.5.2 and 4.5.5.

The third assertion is clear if $c \in \mathcal{O}^*_\mathfrak{p}$. Hence one only has to discuss the case that ord$_{\mathfrak{p}}(c) = 1$. But then, one may assume that $c \in K^*$ is totally positive and $c\mathcal{O} = \mathfrak{p}\mathcal{O}$ for some good prime ideal $\mathfrak{q}$ of $\mathcal{O}$ such that $L_{\mathfrak{q}}$ is unimodular. Then $\lambda(L_{\mathfrak{q}}^c) = \lambda(L_{\mathfrak{q}})$ for all $\mathfrak{a} \in \mathbb{P}(\mathcal{O}) - \{\mathfrak{p}, \mathfrak{q}\}$ and also for $\mathfrak{a} = \mathfrak{q}$ by Lemma 4.2.9. Moreover, $L$ and $L^c$ have the same mass. But then the formulation of Siegel’s mass formula given in Proposition 4.2.7 shows that $\lambda(L_{\mathfrak{p}}) = \lambda(L_{\mathfrak{p}}^c)$. \qed
4.3 Comparing local factors

The purpose of this section is to present a practical method to compare the local factors of two $\mathcal{O}$-lattices in $(V, \Phi)$. This result will be employed later to compute the missing local factors of square-free lattices whenever $\dim_K(E) = 2$. The method is taken from the article [BN97] of Ch. Bachoc and G. Nebe and it can also be deduced from Section 17 of M. Eichler’s book [Eic52]. I would like to thank R. Schulze-Pillot for pointing out this reference.

In this section, $p$ always denotes a prime ideal of $\mathfrak{o}$.

**Definition 4.3.1** Given $\mathcal{O}_p$-lattices $M$ and $L$ in $(V, \Phi)$ the following two sets of lattices are defined:

$D(L, M) = \{X \subseteq L \mid X \text{ an } \mathcal{O}_p\text{-lattice isometric to } M\}$,

$U(L, M) = \{X \supseteq M \mid X \text{ an } \mathcal{O}_p\text{-lattice isometric to } L\}$.

**Remark 4.3.2** Let $M \subseteq L$ be $\mathcal{O}_p$-lattices in $(V, \Phi)$. Taking duals induces bijections

$D(L, M) \leftrightarrow U(M^\#, L^\#)$ and $U(L, M) \leftrightarrow D(M^\#, L^\#)$.

Hence, the computation of $D$ can be turned into the computation of some suitable set $U$. The latter is usually more convenient to compute.

**Definition 4.3.3** Let $a$ be a fractional ideal of $\mathfrak{o}$. Given any $\mathcal{O}$-lattice $L$ in $(V, \Phi)$, let

$aL := \{x \in L \mid \Phi(x, x) \in a\}$.

A similar definition is made for $\mathcal{O}_p$-lattices in $(V, \Phi)$.

**Remark 4.3.4** Let $a$ be a fractional ideal of $\mathfrak{o}$ and let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$. Then $aL$ is an $\mathcal{O}$-lattice if and only if $T(s(L)) \subseteq a$. If this is the case, then $aL$ is the maximal $\mathcal{O}$-sublattice of $L$ with norm contained in $a$ and thus $\#D(L_p, aL_p) = 1$ for all $p \in \mathfrak{P}(\mathfrak{o})$.

**Proposition 4.3.5** Let $L$ and $M$ be $\mathcal{O}$-lattices in $(V, \Phi)$ such that $M_p \subseteq L_p$. Then

$\lambda(M_p) \cdot \#U(L_p, M_p) = \lambda(L_p) \cdot \#D(L_p, M_p)$.

**Proof.** The proof follows [BN97] and [Eic52, S. 111]. Without loss of generality, $L_q = M_q$ for all prime ideals $q \neq p$ of $\mathfrak{o}$. So by Proposition 4.2.10/5, it suffices to show that

$\Mass(M) \cdot \#U(L_p, M_p) = \Mass(L) \cdot \#D(L_p, M_p)$.

Let $L_1, \ldots, L_h$ and $M_1, \ldots, M_s$ represent the isometry classes in $\text{gen}(L)$ and $\text{gen}(M)$ respectively. Further, let

$a_{ij} = \#\{X \subseteq L_i \mid X \text{ an } \mathcal{O}\text{-lattice isometric to } M_j\}$,

$b_{ji} = \#\{X \supseteq M_j \mid X \text{ an } \mathcal{O}\text{-lattice isometric to } L_i\}$.
Then \( \sum_j a_{ij} = \#D(L_p, M_p) \) and similarly \( \sum_i b_{ji} = \#U(L_p, M_p) \). Suppose \( \varphi, \varphi' \in U(V, \Phi) \) such that \( \varphi(M_j), \varphi'(M_j) \subseteq L_i \) with \( \varphi(M_j) = \varphi'(M_j) \). Then \( \varphi^{-1} \circ \varphi' \in \text{Aut}(M_j) \) and thus

\[
    a_{ij} \cdot \# \text{Aut}(M_j) = \# \{ \varphi \in U(V, \Phi) \mid \varphi(M_j) \subseteq L_i \} = \# \left\{ \psi \in U(V, \Phi) \mid M_j \subseteq \psi(L_i) \right\} = b_{ji} \cdot \# \text{Aut}(L_i).
\]

Putting everything together, one obtains

\[
    \#D(L_p, M_p) \cdot \text{Mass}(L) = \sum_{j=1}^{s} \sum_{i=1}^{h} \frac{a_{ij}}{\# \text{Aut}(L_i)} = \sum_{j=1}^{s} \sum_{i=1}^{h} \frac{b_{ji}}{\# \text{Aut}(M_j)} = \#U(L_p, M_p) \cdot \text{Mass}(M)
\]

as claimed. \( \square \)

**Corollary 4.3.6** Let \( L \) be an \( \mathcal{O} \)-lattice in \( (V, \Phi) \). Then \( \lambda(L_p) \in \mathbb{Q} \) for all \( p \in \mathbb{P}(\mathfrak{o}) \).

**Proof.** By Proposition 4.2.10 one may assume that \( L \) is integral. So \( L \) is contained in some \( \mathfrak{o} \)-maximal lattice \( M \). Then \( \lambda(M_p) \in \mathbb{Q} \) by work of G. Shimura [Shi97, Shi99a, Shi99b], see also [GHY01]. But then \( \lambda(L_p) \in \mathbb{Q} \) by Proposition 4.3.5. \( \square \)

### 4.4 Local factors of unimodular quadratic lattices

Let \( (V, \Phi) \) be a definite quadratic space of dimension \( m \) over \( E = K \). The local factors of (unimodular) \( \mathfrak{o} \)-lattices in \( (V, \Phi) \) are known at all good primes, c.f. Lemma 4.2.9. The purpose of this section is to work out the local factors of unimodular lattices at any prime ideal \( p \) over 2.

The norm and the ramification index of \( p \) will be denoted by \( q \) and \( e \) respectively. Further, let \( p \) be a uniformiser of \( p \). Let \( M \) be a 2\( \mathfrak{o}_p \)-maximal \( \mathfrak{o}_p \)-lattice in \( (V_p, \Phi) \). Given any unimodular \( \mathfrak{o}_p \)-lattice \( L \) in \( (V_p, \Phi) \), let

\[
    \lambda'(L) := \lambda(L)/\lambda(M).
\]

The factor \( \lambda(M) \) is well known by the work of G. Shimura and only depends on the isometry type of \( (V_p, 2\Phi) \):

**Theorem 4.4.1** Let \( M \) be an \( \mathfrak{o}_p \)-lattice in \( (V_p, \Phi) \) and let \( d = \text{disc}(V_p, \Phi) \). If \( M \) is \( p^k \)-maximal, then \( \lambda(M) \) is given by the following table.

<table>
<thead>
<tr>
<th>( m )</th>
<th>( \omega(V_p, p^k\Phi) )</th>

4.4 Local factors of unimodular quadratic lattices

Proof. See Shimura [Shi99a] or Gan-Hanke-Yu [GHY01]. □

Proposition 4.4.2 Let \( L = L_0 \perp L_1 \) be an integral \( \mathfrak{a}_p \)-lattice in \((V_p, \Phi)\) such that \( L_0 \) is unimodular, \( n(L_0) = 2\mathfrak{a}_p \) and \( n(L_1) \subseteq \mathfrak{a}_p \).

1. The map

\[
Q : L_0/\mathfrak{p}L_0, \ x + \mathfrak{p}L_0 \mapsto Q_\Phi(x)/2 + \mathfrak{p}
\]

is a well-defined quadratic form on the \( \mathfrak{a}/\mathfrak{p} \)-space \( L_0/\mathfrak{p}L_0 \).

2. For any primitive vector \( w \in L_0 \), set \( L_w := \{ x \in L : \Phi(x, w) \in \mathfrak{p} \} \). Let \( v \in L_0 \) be a fixed primitive vector. If \( \text{ord}_p(Q_\Phi(v)) = e \), let \( X \) denote the set of anisotropic lines in \((L_0/\mathfrak{p}L_0, Q)\), otherwise let \( X \) denote the set of all isotropic lines. Then

\[
\sigma : X \to D(L, L_v), \ (w + \mathfrak{p}L_0) \mapsto L_w
\]

is a bijection.

Proof. The first assertion is clear. For the proof of the second, note that \( \sigma \) does not depend on the representative \( w \). Suppose now that \( (w + \mathfrak{p}L_0) \in X \). There exists some isometry in \( \text{O}(L_0/\mathfrak{p}L_0, Q) \) that maps \( (v + \mathfrak{p}L_0) \) to \( (w + \mathfrak{p}L_0) \). By [Kne02, Satz 15.6], it lifts to some isometry of \( L_0 \) and therefore to some element \( \varphi \in \text{Aut}(L) \). Thus \( L_w = L_\varphi(v) = \varphi(L_v) \in D(L, L_v) \). Hence \( \sigma \) is well-defined. Since \( L_0 \) is unimodular, the map \( \sigma \) is also one to one. It remains to show that it is onto. Let \( M \in D(L, L_v) \). Then there exists some \( \varphi \in \text{O}(V_p, \Phi) \) such that \( \varphi(L_v) = M \). Let \( w := \varphi(v) \). From \( v \in L_v \) it follows that \( w \in M \subseteq L \). Hence, \( w = w_0 + w_1 \) for some \( w_1 \in L_i \). Then \( M = \varphi(L_v) = L_w = L_{w_1} \). Further, \( Q_\Phi(v) \in 2\mathfrak{p} \iff Q_\Phi(w_0) \in 2\mathfrak{p} \). Thus \( (w_0 + \mathfrak{p}L_0) \in X \).

Since the number of (an)isotropic lines in regular quadratic spaces over finite fields are well known (see for example [Kne02, Section IV.13]), the above proposition can be made effective.

Corollary 4.4.3 Suppose the notation of Proposition 4.4.2. Let \( m_0 \) be the rank of \( L_0 \) and let \( r = \lfloor \frac{m_0}{2} \rfloor \). Then

\[
\#D(L, L_v) = (q - 1)^{-1} \cdot \begin{cases} 
(q^r - \varepsilon)(q^{m_0 - r - 1} + \varepsilon) & \text{if } \text{ord}_p(Q_\Phi(v)) > e, \\
q^{m_0} - 1 - (q^r - \varepsilon)(q^{m_0 - r - 1} + \varepsilon) & \text{if } \text{ord}_p(Q_\Phi(v)) = e,
\end{cases}
\]

\[
= \begin{cases} 
(q - 1)^{-1}(q^r - \varepsilon)(q^{m_0 - r - 1} + \varepsilon) & \text{if } \text{ord}_p(Q_\Phi(v)) > e, \\
q r^{-1} (q^r - \varepsilon) & \text{if } \text{ord}_p(Q_\Phi(v)) = e \text{ and } m_0 \text{ is even,} \\
q^{m_0 - 1} & \text{if } \text{ord}_p(Q_\Phi(v)) = e \text{ and } m_0 \text{ is odd,}
\end{cases}
\]

where \( \varepsilon = -1 \) if \((L_0/\mathfrak{p}L_0, Q)\) is non-hyperbolic of even degree, and \( \varepsilon = +1 \) otherwise.
Theorem 4.4.4 Let $L$ be a unimodular $\mathfrak{o}_p$-lattice in $(V_p, \Phi)$ of weight $p^b$. Suppose that $m = \dim_K(V) = 2r + 1$ is odd. Then

$$
\lambda'(L) = \begin{cases}
1 & \text{if } b = e, \\
(q^r - \omega(V_p, \Phi))q^{r(e-b-1)} & \text{if } e > b \text{ and } e \text{ is odd}, \\
\frac{1}{2}(q^{2r} - 1)q^{r(e-b-1)} & \text{if } e > b, \ e \text{ is even and } \omega(V_p, \Phi) = +1, \\
(q + 1)q^{r(e-b-1)} & \text{if } e > b, \ e \text{ is even and } \omega(V_p, \Phi) = -1.
\end{cases}
$$

Proof. Let $\Delta = 1 - 4\varrho \in \mathfrak{o}^*$ such that $\mathfrak{o}(\Delta) = 4\varrho \mathfrak{o} = 4\varrho$. If $\omega(V_p, \Phi) = 1$ set $\delta = 0$, otherwise set $\delta = \varrho$. There exists some Jordan decomposition $L = \langle x, y \rangle \perp \langle z \rangle \perp H$ where $G(x, y) = A(p^b, 4\delta p^{-b})$ and $Q_\Phi(z) \in \mathfrak{o}^*$ and $H \cong H(0)^{r-1}$.

Suppose first that $b = e$. Then $2\mathfrak{v}L \subseteq L \subseteq (2\mathfrak{v}L)'$ and the quotient $(2\mathfrak{v}L)'/2\mathfrak{v}L$ is cyclic. Thus $\lambda'(L) = \lambda'(2\mathfrak{v}L) = 1$ since $2\mathfrak{v}L$ is $2\mathfrak{o}_p$-maximal.

From now on, it is assumed that $b < e$. By Proposition 3.3.8 this implies that $b$ is odd. Let $M_1 = p^bL$ and $M_2 = b^{b+1}L$. Then again $\lambda'(L) = \lambda'(M_1)$ since $M_1^{\#}/M_2$ is cyclic. Suppose $X \in U(M_1, M_2) \setminus \{M_1\}$. Then $X = (M_2, v)$ for some $v \in M_2^{\#} \cap p^{-1}M_2$. Together with $Q_\Phi(v)\mathfrak{o} = n(M_1) = p^b$ this shows that one can assume $v = \mu x + p^{-1}y$ for some $\mu \in \mathfrak{o}$. Further, $Q_\Phi(v)\mathfrak{o} = p^b$ shows that $\mu \notin p$ if $b \leq e - 2$ and $\mu + 2p^{-e} \notin p$ if $b = e - 1$ and $\omega(V_p, \Phi) = 1$. Conversely, Theorem 3.3.13 shows that all parameters $\mu$ satisfying these conditions yield a lattice $X$ isometric to $M_1$. Hence

$$
\lambda'(L) = \lambda'(M_2) \cdot \begin{cases}
q - \omega(V_p, \Phi) & \text{if } b = e - 1, \\
q & \text{if } b \leq e - 2.
\end{cases}
$$

If $b = e - 1$ and $\omega(V_p, \Phi) = -1$ then Remark 3.1.4/2 shows that $M_2$ is $2\mathfrak{o}_p$-maximal and therefore $\lambda'(L) = q + 1$. Suppose now $b = e - 1$ and $\omega(V_p, \Phi) = +1$. Then $N := (M_2, p^{-1}y)$ is $2\mathfrak{o}_p$-maximal. Let $X \supseteq M_2$ be an integral lattice of norm $p^{b+1}$ not isometric to $M_1$ such that $[X : M_2]_p = p$. As seen before, there are only two such lattices, namely $N$ and $X' = \langle M_2, -2p^{-e}x + p^{-1}y \rangle$. Hence $U(N, M_2) = \{N, X'\}$. Further, $\#D(N, M_2) = (q - 1)^{-1}(q^{2r} - 1)$ by Corollary 4.4.3 and $N$ is $2\mathfrak{o}_p$-maximal. Hence

$$
\lambda'(L) = (q - 1) \cdot \lambda'(M_2) = (q - 1) \cdot \frac{1}{2} q^{2r} - 1 - 1 \cdot \lambda'(N) = \frac{q^{2r} - 1}{2}.
$$

So only the case $b \leq e - 2$ remains. Let $\tilde{L} = \langle px, p^{-1}y, z \rangle \perp H$. Then $\tilde{L}$ is unimodular with weight $p^{b+2}$. Let $\tilde{M} = p^{b+2}/L$. Then $\lambda'(\tilde{L}) = \lambda'(\tilde{M})$ as seen before. Let $M_3 = p^{b+2}L$.

Using similar arguments as before, one obtains $\#U(M_2, M_3) = 1 = \#U(M, M_3)$. Thus

$$
\lambda'(L) = q \cdot \lambda'(M_3) = q \cdot \#D(\tilde{M}, M_3) \cdot \lambda'(\tilde{L}).
$$

So it remains to compute $\#D(\tilde{M}, M_3) = \#U(M_3^{\#}, \tilde{M}^{\#})$. If $b = e - 2$, then $\#D(\tilde{M}, M_3) = q^{-1}(q^r - \omega(V_p, \Phi))$ by Corollary 4.4.3. Suppose now $b < e - 2$ and $X \in U(M_3^{\#}, \tilde{M}^{\#})$. The conditions $n(X) = n(M_3^{\#}) = p^{-b-3} + p^{-2}$ and $n(X^{p^{-1}}) = n((M_3^{\#})^{p^{-1}}) = p^b$ imply that
4.4 Local factors of unimodular quadratic lattices

Let $X = (\tilde{M}^#, v)$ with $v = x + \mu p^{-1} y + p^{-1} h$ where $\mu \in \mathfrak{o}$ and $h \in H$. Conversely, by Theorem 3.3.13, each such vector $v$ yields some lattice in $U(M^#, \tilde{M}^#)$. Hence $\#D(M, M_3) = q^{2r-1}$ and therefore $\lambda'(L) = q^{2r} \cdot \lambda'(\tilde{L})$. The result now follows by induction on $b$. 

To simplify the presentation of the local factors, the following symbol will be used:

**Definition 4.4.5** Given a unimodular lattice $L$ in $(V_p, \Phi)$ let

$$
\varepsilon(L) = \begin{cases} 
+1 & \text{if } \mathfrak{o}(\text{disc}(L)) = (0), \\
-1 & \text{if } \mathfrak{o}(\text{disc}(L)) = 4\mathfrak{o}_p, \\
0 & \text{otherwise.}
\end{cases}
$$

**Theorem 4.4.6** Let $L$ be a unimodular $\mathfrak{o}_p$-lattice in $(V_p, \Phi)$. Further, let $n(L) = p^a$, $w(L) = p^b$ and $\mathfrak{o}(\det(L_p)) = p^c$. If $m = \dim_K(V) = 2$, then

$$
\lambda'(L) = \begin{cases} 
q^{\lfloor e - a - 1/2 \rfloor} (q - \varepsilon(L)) & \text{if } a < b = e \leq c/2, \\
2q^{\lfloor e - a - 2/2 \rfloor} & \text{if } b = e \text{ and } a + e + 1 \leq c < 2e, \\
1 & \text{otherwise.}
\end{cases}
$$

**Proof.** Propositions 3.3.8 and 3.3.11 show that $c \geq a + b \geq 2a$. Moreover, if $a = b$ then $a = e$. So $L$ is $2\mathfrak{o}_p$-maximal in that case and therefore $\lambda'(L) = 1$. Similarly, if $c = 2a + 1$, then $b = a + 1$ and $L$ is $p^a$-maximal. In any of these two cases, Theorem 4.4.1 shows that $L$ has the same local density then any $2\mathfrak{o}_p$-maximal lattice in $(V_p, \Phi)$. Hence $\lambda'(L) = 1$.

Suppose now $a \leq e - 1$ and $c \geq 2a + 2$. Let $\alpha, \gamma$ be as in Proposition 3.3.11 and fix some basis $(x, y)$ of $L$ with Gram matrix $A(\alpha, -\gamma \alpha^{-1})$. Let $M := p^{a+1} L = \langle px, y \rangle$. Remark 4.3.4 shows

$$
\lambda'(L) = \#U(L, M) \cdot \lambda'(M).
$$

The rescaled lattice $M^{p-1}$ has norm generator $p\alpha$, determinant $-(1 + \gamma)$ and weight $p^{b'}$ where $b' = b - 1$ if $c = a + b$ and $b' = e$ otherwise. So once $\#U(L, M)$ has been worked out, one can finish the proof by induction on $a$.

Suppose first $a = e - 1$. Then $b = e$ and the case $c = 2e - 1$ has already been discussed above, which leaves $c \geq 2e$. Then $(M^{\#})^p$ is unimodular and Corollary 4.4.3 shows that

$$
\#U(L, M) = \#D((M^{\#})^p, L^p) = q - \omega(V_p, \Phi).
$$

So only the case where $a \leq e - 2$ and $c \geq 2a + 2$ remains. Let $L' \in U(L, M)$. Then $L' = \langle M, v/p \rangle$ for some $v \in M$. Write $v = \mu p x + \nu y$ with $\mu, \nu \in \mathfrak{o}$. Then $n(L') = p^a$ implies $\mu \in \mathfrak{o}^*$ and so one may assume that $\mu = 1$. Then $L$ and $L'$ are both unimodular, have weight $p^b$ and norm generators $\alpha$ and $\alpha' := \Phi(x + \nu y/p, x + \nu y/p)$ respectively. Theorem 3.3.13 shows that $L \cong L'$ if and only if the quadratic defect of

$$
\alpha'/\alpha = 1 + 2\nu\alpha^{-1}/p - \nu^2\gamma\alpha^{-2}/p^2
$$

61
is contained in $\mathfrak{p}^{b-a}$. A case by case discussion yields

$$\#U(L, M) = \begin{cases} 2 & \text{if } b = e \text{ and } c = e + a + 1, \\ q & \text{if } b = e \text{ and } e - a \text{ is odd and } c > e + a + 1, \\ 1 & \text{otherwise.} \end{cases}$$

The result now follows by induction on $a$. \hfill \square

As a consequence of the previous result, one obtains the mass factors for unimodular lattices $L$ where $\text{ord}_p(n(L)\mathfrak{m}(L))$ is even.

**Lemma 4.4.7** Let $L = L_1 \perp L_2$ be an $\mathfrak{a}_p$-lattice in $(V_p, \Phi)$. Suppose that $L_2$ is unimodular with $n(L_2) = 2\mathfrak{a}_p$ and $L_1$ is a $p^s$-modular binary lattice such that $s < 0$ and $\mathfrak{o}(-\det(L_1)) \subseteq 2p^{2s+1}n(L)$. Further let $x \in L_1$ such that $Q_\Phi(x)\mathfrak{o} = n(L_1)$ and let $z \in L_2$. Let $M_1 := \langle (x+z)/p, L_1 \rangle$ and $M := \langle (x+z)/p, L \rangle$. Then there exists some splitting $M = M_1 \perp M_2$. Moreover, $M_2 \cong L_2$ and $M_1 \cong \langle x/p, y \rangle$.

**Proof.** The condition $s < 0$ implies that $M_2$ exists, c.f. [O’M73, 82:15] for details. Let $\alpha = Q_\Phi(x) \cdot p^{-2s}$ and write $-\det(L_1) = p^{2s}(1 + \gamma)$ where $\gamma p^{2s} = \mathfrak{o}(-\det(L))$. By [O’M73, Example 93:17], there exists some $y \in L_1$ such that $L_1 = \langle x, y \rangle$ and $G(x, y) = p^s A(\alpha, -\gamma \alpha^{-1})$. The lattices $X := \langle x/p, y \rangle$ and $L_1$ are both $p^{s-1}$-modular. The assumption on $\mathfrak{o}(-\det(L_1))$ implies that $\det(M_1) = \det(X)$ and thus $\det(M_2) = \det(L_2)$. In particular, the quadratic spaces $KL_1$ and $KM_1$ are isometric. Thus $KM_2$ is isometric to $KL_2$. From the description

$$M_2 = \{ m\gamma \alpha^{-1}(x+z) + my + v \mid v \in L_2 \text{ and } m = \frac{-\Phi(v,z)}{\gamma \alpha^{-1}Q_\Phi(z) + (1+\gamma)p^s} \}$$

and the condition on $\mathfrak{o}(-\det(L_1))$ it is easy to check that $M_2$ is integral and $n(M_2) \subseteq 2\mathfrak{a}_p$. Thus $M_2$ and $L_2$ are both unimodular lattices of norm $2\mathfrak{a}_p$ in isometric spaces. Proposition 3.3.11 shows that $M_2 \cong L_2$ as claimed.

It remains to show that $X \cong M_1$. Both lattices have weight $2p^{s-1} + \alpha^{-1}\gamma p^s$ and norm generators $\alpha_1 := \alpha p^{s-2}$ and $\alpha_2 := (\alpha p^s + Q_\Phi(z))p^{-2}$ respectively. A case by case discussion shows that the quadratic defect of $\alpha_2/\alpha_1 = 1 + p^{-s}\alpha^{-1}Q_\Phi(z)$ is contained in $2n(L_1)^{-1} \subseteq \mathfrak{m}(L_1)/n(L_1)$. Hence $X \cong M_1$ by Theorem 3.3.13. \hfill \square

**Lemma 4.4.8** Let $L$ be a unimodular $\mathfrak{a}_p$-lattice in $(V_p, \Phi)$. Suppose $m = \text{dim}_K(V) = 2r$ is even and $L$ admits a splitting $L = \mathcal{L} \perp M$ where $\mathcal{L}$ has rank $2$ and $n(M) = 2\mathfrak{a}_p$. Let $a = \text{ord}_p(n(L)), c = \text{ord}_p(\mathfrak{o}(\text{-det}(\mathcal{L}))), i = \lceil \frac{c-a}{2} \rceil$ and $j = \min\{i, \max\{0, \lceil \frac{c-a}{2} \rceil\}\}$. Then

$$X'(L) = \begin{cases} q^{2r-i-r}(q^r - \varepsilon(L)) & \text{if } c \geq 2e \text{ and } a + e \text{ is even,} \\ \frac{1}{2}q^{(2r-1)(i-1)}(q^r - \varepsilon(L))(q^{r-1} + \varepsilon(L)) & \text{if } c = \infty \text{ and } a + e \text{ is odd,} \\ q^{(i-1)(2r-1)}(q^r + 1) & \text{if } c = 2e \text{ and } a + e \text{ is odd,} \\ 2q^{(2r-1)} & \text{if } a + e + 1 \leq e < 2e, \\ q^{2i(r-1)} & \text{otherwise.} \end{cases}$$
Proof. Let \( \alpha \) be a norm generator of \( \tilde{L} \) and write \( -\det(\tilde{L}) = 1 + \gamma \) with \( \gamma \in \mathfrak{o} \) such that \( \gamma \mathfrak{o} = \mathfrak{d}(-\det(\tilde{L})) \). There exists some basis \( (x, y) \) of \( \tilde{L} \) with \( G(x, y) = \mathbb{A}(\alpha, -\gamma \alpha^{-1}) \).

If \( X \in U(L, 2eL) \) then \( X \subseteq (2eL)^\# = (2e\tilde{L})^\# \perp M \). Thus \( \#U(L, 2eL) = \#U(\tilde{L}, 2e\tilde{L}) \).

For \( 0 \leq t \leq j \) let \( \tilde{L}_t = \langle p^t x, p^{-t} y \rangle \) and \( L_t := \tilde{L}_t \perp M \). Then \( L_0 = 2eL \) and \( L_j \) is \( 2e \)-maximal, i.e. \( \lambda'(L_j) = 1 \). Suppose first that \( X \in U(L_t, L_{i-1}) \) for some \( 1 \leq t \leq j \). Then \( X = (L_{i-1}, v/p) \) for some \( v \in L_{i-1} \). From \( \Phi(v/p, L_{i-1}) \subseteq \Phi(v/p, L_t) \subseteq \mathfrak{o} \), it follows that \( v \in pL_{i-1} \cap L_{i-1} \). Hence one may assume that \( v \in L_{i-1} \).

One checks that unless \( c = \infty \), \( i = \ell \) and \( e - a \) is odd, the condition \( n(X) = n(L_t) \subseteq 2\mathfrak{o} \) implies \( X = L_t \) and thus \( \#U(L_t, L_{i-1}) = 1 \). In the special case that \( c = \infty \) and \( e - a \) is odd, \( L_{i-1} \cong H(1) \) and \( L_{i-1} \) has two overlattices isometric to \( L_i \cong H(0) \). Hence \( \#U(L_i, L_{i-1}) = 2 \) in this exceptional case.

If \( i = j \geq 1 \), then \( c \geq 2e \) and Corollary 4.4.3 shows that

\[
\#D(L_i, L_{i-1}) = \begin{cases} 
q^{r-1}(q^r - \varepsilon(L)) & \text{if } a + e \text{ is even}, \\
(q - 1)^{-1}(q^r - \varepsilon(L))(q^{r-1} + \varepsilon(L)) & \text{if } a + e \text{ is odd}.
\end{cases}
\]

Suppose now \( 1 \leq t \leq \min\{i, j\} \). Then every element in \( U(L_t^\#, L_t^\#) \) is of the form \( \langle (v+w)/p, L_t \rangle \) with \( w \in M \) and \( v \) a norm generator of \( \tilde{L}_t \). In particular, \( \#U(L_t^\#, L_t^\#) = q^{2(r-1)} \cdot \#U(\tilde{L}_t^\#, \tilde{L}_t^\#) \) by Lemma 4.4.7.

Putting everything together yields

\[
\lambda'(L) = \lambda'(\tilde{L}) \cdot \begin{cases} 
q^{2(r-1)(i-1)}q^{r-1}(q^r - \varepsilon(L)) & \text{if } i = j \geq 1 \text{ and } a + e \text{ is even}, \\
q^{2(r-1)(i-1)}q^{r-1}(q^r - \varepsilon(L))(q^{r-1} + \varepsilon(L)) & \text{if } i = j \geq 1 \text{ and } a + e \text{ is odd}, \\
q^{2i(r-1)} & \text{otherwise}.
\end{cases}
\]

Note that the second case can only occur of \( \varepsilon(\tilde{L}) = 1 \). The result now follows from Theorem 4.4.6. \( \square \)

As an immediate consequence from the previous result, one obtains the mass factors of forms of type (II), c.f. Proposition 3.3.11.

**Theorem 4.4.9** Let \( L \) be a unimodular \( \mathfrak{o}_p \)-lattice in \( (V_p, \Phi) \) such that \( \text{ord}_p(n(L)\mathfrak{w}(L)) \) is even. Let \( a = \text{ord}_p(n(L)) \) and \( c = \text{ord}_p(\mathfrak{d}(\text{disc}(L))) \). If \( m = \dim_K(V) = 2r \) is even, then

\[
\lambda'(L) = \begin{cases} 
1 & \text{if } e = a, \\
q^{(e-a)(r-1/2)-r}(q^r - \varepsilon(L)) & \text{if } a < e \leq c/2, \\
2q^{(e-a-1)(r-1/2)} & \text{if } a + e + 1 \leq c < 2c, \\
q^{(c-e-a-1)(r-1)} & \text{otherwise}.
\end{cases}
\]

**Proof.** By Proposition 3.3.11, there exists some splitting \( L = \tilde{L} \perp M \) where \( M \cong H(0)^{r-1} \). The result follows by applying Lemma 4.4.8 to this splitting. \( \square \)
Theorem 4.4.10  Let $L$ be an unimodular $\mathfrak{o}_p$-lattice in $(V_p, \Phi)$ such that $\text{ord}_p(n(L)w(L))$ is odd. Let $a = \text{ord}_p(n(L))$, $b = \text{ord}_p(w(L))$, $c = \text{ord}_p(\mathfrak{o}(\text{disc}(L)))$ and

$$c' = \begin{cases} 
\infty & \text{if } c = 2e \text{ and } L \text{ is of type (IIIb) c.f. Proposition 3.3.11,} \\
2e & \text{if } c = \infty \text{ and } L \text{ is of type (IIIb),} \\
c & \text{otherwise.}
\end{cases}$$

If $m = \dim_K(V) = 2r \geq 4$ is even, then

$$\lambda'(L) = \begin{cases} 
\frac{1}{2}q^{(e-a-1)(r-\frac{1}{2})}q^r - \varepsilon(L)(q^{r-1} + \varepsilon(L)) & \text{if } b = e \text{ and } c' = \infty, \\
q^{(e-a-1)(r-\frac{1}{2})}(q + 1) & \text{if } b = e \text{ and } c' = 2e, \\
\frac{1}{2}q^{(r-\frac{1}{2})t+\tau}(q^r - \varepsilon(L))(q^{2r-2} - \varepsilon(L)) & \text{if } b < e \text{ and } c = c' = \infty, \\
q^{(r-\frac{1}{2})t+r}(q + 1) & \text{if } b < e \text{ and } c \neq c' = \infty, \\
\frac{1}{2}q^{(r-\frac{1}{2})t+\tau}(q^{r-1} + 1)(q^r - \varepsilon(L))(q^{r-1} + \varepsilon(L)) & \text{if } b < e \text{ and } c' = 2e, \\
q^{(r-\frac{1}{2})t+r}(q^{r-1} + 1)(q + 1) & \text{if } b < e \text{ and } c \neq c' = 2e, \\
1 & \text{if } c = a + b, \\
2q^{(c-e-a)(r-\frac{1}{2})} & \text{if } a + b < c < 2b = 2e, \\
q^{(e-a-b-2)(r-\frac{1}{2})+1}(q^{2r-2} - 1) & \text{otherwise}
\end{cases}$$

where $s = 2e - b - a - 3$.

Proof. Let $\Delta = 1 - 4\vartheta \in \mathfrak{o}^*$ such that $\mathfrak{o}(\Delta) = 4\vartheta = 4\vartheta$. If $e = b$ or $c = a + b$, then $L \cong L_1 \perp L_2$ where $L_1$ is binary and $L_2$ is unimodular with $n(L_2) = 2\mathfrak{o}_p$. These cases have been already discussed in Lemma 4.4.8.

Suppose now $b < e$ and $a + b < c$. Let $\alpha$ be a norm generator of $L$. If $L$ is of type (IIIa), let $\delta = 0$, otherwise let $\delta = \varrho$. There exists some splitting $L = \langle x, y \rangle \perp \langle z, w \rangle \perp H$ where $G(x, y) = A(\alpha, -\gamma - 4\varrho \alpha^{-1})$, $G(z, w) = A(p^b, 4\varrho p^{-b})$ and $H \cong H(0)^{r-2}$. Let $M = p^{b+1}L$ and $\tilde{L} = \langle px, p^{-1}y, z, w \rangle \perp H$. One verifies that $\#U(L, M) = q$ and $\#U(\tilde{L}, M) = 1$. Hence $\lambda'(L) = q \cdot \#U(M^#, \tilde{L}) \cdot \lambda(\tilde{L})$.

So it remains to compute $\#U(M^#, \tilde{L})$. The result then follows by induction on $a$ since $n(\tilde{L}) = p^{a+2} + p^b$. Any element $X \in \#U(M^#, \tilde{L})$ is of the form $X = \langle \tilde{L}, v \rangle$ with $v = \mu x + \nu p^{-1}y + \eta p^{-1}z + \tau p^{-1}w + \nu^{-1}h$ where $h \in H$ and $\mu, \nu, \eta, \tau \in \varphi$.

Suppose first that $a < e - 2$ and $c > a + b + 2$. The conditions $\text{ord}_p(Q\varphi(v)) = a$ and $w(X) = p^b$ show that one can assume $\mu = 1$ and $\eta = 0$. Conversely, it follows from Theorem 3.3.13 that any vector $v$ satisfying these two conditions yields some lattice in $U(M^#, \tilde{L})$. Hence $\#U(M^#, \tilde{L}) = q^{2(r-1)}$ in this case.

Suppose now $e = a + 2 = b + 1$ and $c \geq 2e$. The condition $\text{ord}_p(Q\varphi(v)) = a$ shows that one can assume $\eta = 0$. Let $W := \langle x, p^{-2}y, H \rangle$. Then $W/pW$ equipped with the quadratic form $w + pW \mapsto Q\varphi(w) + p^b$ is a regular quadratic space over $\mathfrak{o}/p$ and $(\mu, \nu, h)$ yields an anisotropic line in this space. Conversely, every such line yields some vector $v \in p^{-1}L$ with $\text{ord}_p(Q\varphi(v)) = a$ and thus a lattice $X \in U(M^#, \tilde{L})$ as Theorem 3.3.13 shows. Further, $W/pW$ is hyperbolic if and only if $\gamma = 4\varrho$. Hence [Kne02, Section IV.13]
shows that \( \#U(M^#, \tilde{L}) = q^{r-1}(q^{r-1} - \varepsilon') \) where \( \varepsilon' = 1 \) if \( \gamma = 4\delta \) and \( -1 \) otherwise. Finally, suppose \( c = a + b + 2 \). There exists some splitting \( \tilde{L} = (\tilde{x}, \tilde{y}) \perp (\tilde{z}, \tilde{w}) \perp \tilde{H} \) where \( G(\tilde{x}, \tilde{y}) = A(\alpha p^2, -(\gamma - 4\delta)\alpha^{-1}p^{-2}) \), \( G(\tilde{z}, \tilde{w}) = A(p^c, 4\delta p^{-c}) \) and \( \tilde{H} \cong H(0)^{r-2} \). Any element \( X \in U(M^#, \tilde{L}) \) is of the form \((\tilde{L}, v/p)\) with \( v = \mu \tilde{x} + \nu \tilde{y} + \eta \tilde{w} + \tau \tilde{z} + h \) where \( \mu, \nu, \eta, \tau \in \mathfrak{o} \) and \( h \in \tilde{H} \). The conditions \( n(X) = n(L) \) and \( \mathfrak{m}(X) = \mathfrak{m}(L) \) imply that one may assume \( \mu = 1 \) and \( \nu = 0 \). This leaves at most \( q^{2(r-1)} \) possibilities for \( X \). All of these lattices except \((\tilde{L}, \tilde{x}/p)\) are isometric to \( M^# \) as a direct computation using Theorem 3.3.13 shows. Hence \( \#U(M^#, \tilde{L}) = q^{2(r-1)} - 1 \). \( \square \)

4.5 Local factors of square-free hermitian lattices over ramified dyadic field extensions

Let \( E/K \) be a CM-extension of number fields and let \((V, \Phi)\) be a definite hermitian space of dimension \( m \) over \( E \).

Suppose \( \mathfrak{p} \) is a bad prime ideal of \( \mathfrak{o} \), i.e. \( \mathfrak{p} \mid 2 \) and \( e := \text{ord}_p(d_{E/K}) \geq 2 \). Let \( \mathfrak{P} \) be the prime ideal of \( \mathcal{O} \) above \( \mathfrak{p} \) and set \( q = \text{Nm}_{E/K}(\mathfrak{p}) = \#\mathfrak{o}/\mathfrak{p} \). As before, \( \pi \) denotes a uniformiser of \( \mathfrak{P} \). Then \( p := \pi \mathfrak{P} \) is a uniformiser of \( \mathfrak{p} \).

An \( \mathcal{O} \)-lattice \( L \) in \((V, \Phi)\) will be called square-free, if \( L_\mathfrak{p} = L_0 \perp L_1 \) where \( L_i \) is \( \mathfrak{P}^i \)-modular. These lattices will play an important role in the classification of all lattices with given class number, see Chapter 6 for details.

The purpose of this section is to compare the local density of any square-free \( \mathcal{O}_\mathfrak{p} \)-lattice in \((V_\mathfrak{p}, \Phi)\) with the local density of some maximal lattice. The latter densities have been worked out by G. Shimura [Shi97] and also by W. Gan, J. Hanke and J.-K. Yu [GHY01]:

**Theorem 4.5.1** Let \( M \) be a \( \mathfrak{p}^i \)-maximal \( \mathcal{O}_\mathfrak{p} \)-lattice in \((V_\mathfrak{p}, \Phi)\) for some \( i \in \mathbb{Z} \). Then

\[
\lambda(M) = \begin{cases} 
\frac{1}{2} & \text{if } m \text{ is odd,} \\
1 & \text{if } (V_\mathfrak{p}, \Phi) \text{ is hyperbolic,} \\
\frac{q^{m-1}}{2(q+1)} & \text{otherwise.}
\end{cases}
\]

**Proof.** See Propositions 4.4 and 4.5 of [GHY01]. \( \square \)

If \( m \) is odd, the computation of the local factor \( \lambda(L_\mathfrak{p}) \) is fairly easy.

**Theorem 4.5.2** Let \( L := L_0 \perp L_1 \) be an \( \mathcal{O}_\mathfrak{p} \)-lattice in \((V_\mathfrak{p}, \Phi)\) such that \( L_i \) is \( \mathfrak{P}^i \)-modular. Let \( m_i = \text{rank}(L_i) \). If \( m = m_0 + m_1 \) is odd, then

\[
\lambda(L) = \frac{1}{2} \left( \frac{(m-1)/2}{m_1/2} \right) q^2.
\]

**Proof.** For \( 0 \leq r \leq (m-1)/2 \) let \( L_r \) be an \( \mathcal{O}_\mathfrak{p} \)-lattice in \((V_\mathfrak{p}, \Phi)\) such that

\[
L_r \cong \langle 1 \rangle \perp H(0)^r \perp H(1)^s \quad \text{where } s = \frac{(m-1)}{2} - r.
\]  

(4.5.1)
Theorem 3.3.18 shows that $L$ is similar to $L_{(m_0-1)/2}$. Let

$$(x_0, x_1, y_1, \ldots, x_r, y_r, x'_1, y'_1, \ldots, x'_s, y'_s)$$

be a basis of $L_r$ corresponding to the orthogonal decomposition given in equation (4.5.1). First the local factors $\lambda(L_r)$ and $\lambda(L_{r+1})$ will be compared. The lattices in $U(L_{r+1}, L_r)$ are precisely the lattices of the form $\langle L_r, x/\pi \rangle$ where $x$ is a primitive vector in $\langle x'_1, x'_2, \ldots, x'_s, y'_s \rangle$. Thus $\#U(L_{r+1}, L_r) = (q - 1)^{-1}(q^{(m-1)-2r} - 1)$. Similarly, one checks that

$$\#D(L_{r+1}, L_r) = \#U(L_r^\#, L_{r+1}^\#) = (q - 1)^{-1}(q^{2(r+1)} - 1).$$

Thus

$$\lambda(L_r) = \lambda(L_{(m-1)/2}) \cdot \prod_{i=r}^{(m-3)/2} \frac{q^{2(i+1)} - 1}{q^{(m-1)/2} - 1} = \lambda(L_{(m-1)/2}) \cdot \left(\frac{(m-1)/2}{(m-1)/2 - r}\right) q^2$$

and

$$\lambda(L_r) = \lambda(L_0) \cdot \prod_{i=0}^{r-1} \frac{q^{(m-1)/2} - 1}{q^{2i+2} - 1} = \lambda(L_0) \cdot \left(\frac{(m-1)/2}{(m-1)/2 - r}\right) q^2.$$

Hence it suffices to show that $\lambda(L_0) = 1/2$ or $\lambda(L_{(m-1)/2}) = 1/2$. Suppose first that $e$ is even and set $f = e/2$. To ease notation, write $M$ for $L_{(m-1)/2}$. Then $p^f M$ is $p^f$-maximal and $\#D(M, p^f M) = 1$ as explained in Remark 4.3.4. Conversely, $\#U(M, p^f M) = 1$ since $(p^f M)^\# / p^f M$ is cyclic. Thus $\lambda(L_{(m-1)/2}) = \lambda(p^f M) = 1/2$ by Theorem 4.5.1. Suppose now that $e$ is odd and set $f = (e+1)/2$. Using the basis of $L_0$ from above, let $M_1 := \langle x_0, x'_1, y'_1, \ldots, x'_s, y'_s \rangle$ and $M = \langle \pi^f x_0 \rangle \perp M_1$. Then $\#D(M, L_0) = 1$ as $M$ is the unique maximal sublattice of $L_0$ with norm $p^f$. Conversely, for $0 \leq i < f$, $\langle \pi^i x_0 \rangle \perp M_1$ is the only superlattice of $\langle \pi^{i+1} x_0 \rangle \perp M_1$ which is isometric to $(\pi^i \pi^n) \perp H(1)^{(m-1)/2}$. Whence $\lambda(L_0) = \lambda(M)$. Further, $M$ is $p^f$-maximal and therefore $\lambda(L_0) = \lambda(M) = 1/2$ by Theorem 4.5.1. This finishes the proof.

If $m$ is even, the computation of local densities is much more involved. First, an analogue to Proposition 4.4.2 is given.

**Theorem 4.5.3** Let $i \in \mathbb{Z}$ such that $e + i$ is odd and set $f = \frac{e+i-1}{2}$. Let $L = L_0 \perp L_1$ be an $\mathcal{O}_p$-lattice in $(V_p, \Phi)$ such that $L_0$ is $\mathfrak{P}^f$-modular and rank$(L_0) \geq 2$ is even. Suppose $n(L_0) = p^f$ and $n(L_1) \leq p^{f+1}$.

1. Let $L_0'$ denote the $\mathfrak{o}/p$-space $L_0/\mathfrak{P}L_0$. Then

$$Q: L_0' \to \mathfrak{o}/p, \quad x + \mathfrak{P}L_0 \mapsto p^{-f} Q_{\mathfrak{o}}(x) + p$$

is a well defined quadratic form on $L_0'$.
2. Given any primitive vector \( w \in L_0 \), set \( L_w := \{ x \in L : \Phi(x, w) \in \mathfrak{P}^{i+1} \} \). Let \( v \) be a fixed primitive vector of \( L_0 \). If \( Q(v + \mathfrak{P}L_0) = 0 \) let \( X \) denote the set of all isotropic lines in \( (L_0, Q) \). Otherwise let \( X \) denote the set of all anisotropic lines of \( (L_0, Q) \). Then
\[
\sigma : X \to D(L, L_v), \langle w + \mathfrak{P}L_0 \rangle \mapsto L_w
\]
is a bijection.

Proof. 1. The map \( Q \) is well defined since \( T(\pi \Phi(x, y)) \in T(\mathfrak{P}^{i+e+1}) = \mathfrak{p}^{f+1} \) for all \( x, y \in L \). Further,
\[
(x + \mathfrak{P}L_0, y + \mathfrak{P}L_0) \mapsto Q(x + y + \mathfrak{P}L_0) - Q(x + \mathfrak{P}L_0) - Q(y + \mathfrak{P}L_0) = p^{-f}T(\Phi(x, y)) + \mathfrak{p}
\]
is bilinear and thus \( Q \) is a quadratic form.

2. The most difficult part is to show that \( \sigma \) is well defined. Let \( \langle w + \mathfrak{P}L_0 \rangle \in X \). The map \( \sigma \) does not depend on the chosen representative \( w \). By Witt’s theorem, there exists some automorphism \( \varphi' \in \text{Aut}(L'_0, Q) \) such that \( \varphi'(w + \mathfrak{P}L_0) = w + \mathfrak{P}L_0 \), see for example [Kne02, Satz 3.4] for details. Hence there exists some \( \mathcal{O} \)-linear map \( \varphi_1 : L_0 \to L_0 \) such that \( \varphi_1(v) + \mathfrak{P}L_0 = w + \mathfrak{P}L_0 \) and \( \Phi(\varphi_1(x), \varphi_1(y)) - \Phi(x, y) \in \mathfrak{p}^{1+f} \) for all \( x, y \in L_1 \). To show that \( L_w \in D(L, L_v) \), the map \( \varphi' \) will be lifted to some (hermitian) automorphism of \( L_0 \) using arguments similar to [Kne02, Section V.15]. Suppose there exists some \( \mathcal{O} \)-linear lift \( \varphi_k : L_0 \to L_0 \) of \( \varphi' \) such that
\[
Q_k(\varphi_k(x)) - Q_k(x) \in \mathfrak{p}^{k+f} \quad \text{for all } x \in L_0.
\]
Define
\[
Q_k : L'_0 \to \mathfrak{o}/\mathfrak{p}, \quad (x + \mathfrak{P}L_0) \mapsto p^{-k-f}(Q_k(\varphi_k(x)) - Q_k(x)) + \mathfrak{p}.
\]
As before, the map \( Q_k \) is well-defined since \( e + i \) is odd. Further,
\[
Q_k(x + y) - Q_k(x) - Q_k(y) = p^{-k-f}T(\Phi(\varphi_k(x), \varphi_k(y)) - \Phi(x, y)) + \mathfrak{p} \quad \text{for all } x, y \in L_0
\]
defines a bilinear form on \( L'_0 \). Hence \( Q_k \) is a quadratic form on \( L'_0 \). So there exists some (not necessarily symmetric) bilinear form \( \Psi : L'_0 \times L'_0 \to \mathfrak{o}/\mathfrak{p} \) such that
\[
Q_k(x + \mathfrak{P}L_0) = \Psi(x + \mathfrak{P}L_0, x + \mathfrak{P}L_0) \quad \text{for all } x \in L_0.
\]
The assumption that \( L_0 \) is \( \mathfrak{P}^j \)-modular implies that
\[
L'_0 \times L'_0 \to \mathfrak{o}/\mathfrak{p}, \quad (x + \mathfrak{P}L_0, y + \mathfrak{P}L_0) \mapsto p^{-f}T(\Phi(x, y)) + \mathfrak{p}
\]
is bilinear and non-degenerate. In particular, given any element \( b \) in some \( \mathcal{O} \)-basis \( B \) of \( L_0 \), there exists some \( v_b \in L_0 \) such that
\[
\Psi(x + \mathfrak{P}L_0, b + \mathfrak{P}L_0) = -p^{-f}T(\Phi(x, v_b)) + \mathfrak{p} \quad \text{for all } x \in L_0.
\]
(4.5.2)
Let \( v : L_0 \to L_0 \) be the \( \mathcal{O} \)-linear map defined by \( v(b) = v_b \) and set \( \varphi_{k+1} := \varphi_k + p^kv \).
Equation (4.5.2) shows that
\[
Q_k(\varphi_k(x)) - Q_k(x) + p^kT(\Phi(x, v(x))) \in \mathfrak{p}^{k+1+f} \quad \text{for all } x \in L_0.
\]
But this is equivalent to
\[ Q_\Phi(\varphi_{k+1}(x)) - Q_\Phi(x) \in p^{k+1+f} \quad \text{for all } x \in L_0. \]

Proceeding in this way, one obtains a sequence \((\varphi_k)\) of \(O\)-linear maps on \(L_0\). Remark 2.1.6 shows that \(\varphi := \lim_{k \to \infty} \varphi_k\) is an isometry of \(EL_0\) and thus injective. It is surjective since \(\varphi(L_0)\) and \(L_0\) are both unimodular. Let \(\varphi' \in \text{Aut}(L)\) be any extension of \(\varphi \in \text{Aut}(L_0)\). Then \(\langle \varphi'(v) + \mathcal{P}L_0 \rangle = \langle w + \mathcal{P}L_0 \rangle\) and therefore \(L_w = \varphi'(L_w) \in D(L, L_v)\) as claimed.

Further, \(\sigma\) is injective since \(L_0\) is \(\mathcal{P}^1\)-modular. If \(M \in D(L, L_v)\), there exist some isometry \(\tau \in U(V, \Phi)\) with \(M = \tau(L_v)\). Write \(\tau(v) = v_0 + v_1\) with \(v_1 \in L_i\). Then \(M = L_{\tau(v)} = L_{v_0}\). The assumption on \(n(L_1)\) implies that \(Q(v + \mathcal{P}L_0) = Q(v_0 + \mathcal{P}L_0)\) and therefore \(\langle v_0 + \mathcal{P}L_0 \rangle \in X\). So \(\sigma\) is surjective.

Again, using [Kne02, Section IV.13], the previous result can be made effective.

**Corollary 4.5.4** In the situation of Theorem 4.5.3, one has
\[
\#D(L, L_v) = \begin{cases} 
q^{k-1}(q^k - \varepsilon) & \text{if } \text{ord}_p(Q_\Phi(v)) = \frac{e+1}{2}, \\
(q-1)^{-1}(q^k - \varepsilon)(q^{k-1} + \varepsilon) & \text{otherwise}, 
\end{cases}
\]
where \(k = \frac{1}{2} \text{rank}(L_0), \varepsilon = +1\) if \(EL_0\) is hyperbolic and \(\varepsilon = -1\) otherwise.

**Theorem 4.5.5** Let \(L_p = L_0 \perp L_1\) be an \(O_p\)-lattice in \((V_p, \Phi)\) such that \(L_i\) is \(\mathcal{P}^i\)-modular. Write \(\ell_0 := \text{ord}_p(n(L)), \ell_1 := \text{ord}_p(n(\mathcal{P}L_0 \perp L_1))\) and \(m_i := \text{rank}(L_i)\). If \(m = m_0 + m_1\) is even, then
\[
\lambda(L) = \frac{c}{2} \left( \frac{m/2}{m_0/2} \right) q^2,
\]
where \(c \in \mathbb{N}\) is given as follows:

1. If \(L_p \cong H(0)^{m_0/2} \perp H(1)^{m_1/2}\), then \(c = \begin{cases} \frac{q^{m_1}}{2} + 1 & \text{if } e \text{ is even}, \\
\frac{q^{m_0}}{2} + 1 & \text{if } e \text{ is odd}. \end{cases}\)

2. If \((V_p, \Phi)\) is hyperbolic and \(L_p \cong H(0)^{m_0/2} \perp H(1)^{m_1/2}\), then
\[
c = \begin{cases} 
q^{m(e/2-\ell_0)-m_1/2(q^{m_1} - 1)} & \text{if } \ell_0 = \ell_1 \text{ and } e \text{ is even}, \\
q^{m(e/2-1-\ell_0)+m_1/2(q^{m_0} - 1)} & \text{if } \ell_0 \neq \ell_1 \text{ and } e \text{ is even}, \\
q^{m(e-1)/2-\ell_0)+m_0/2(q^{m_1} - 1)} & \text{if } \ell_0 = \ell_1 \text{ and } e \text{ is odd}, \\
q^{m(e-1)/2-\ell_0)-m_0/2(q^{m_0} - 1)} & \text{if } \ell_0 \neq \ell_1 \text{ and } e \text{ is odd}. \end{cases}
\]

3. If \((V_p, \Phi)\) is non-hyperbolic, then
\[
c = \begin{cases} 
q^{m_1/2 - 1} & \text{if } \ell_0 = \ell_1 = e/2 \text{ and } e \text{ is even}, \\
q^{m(e/2-\ell_0)-m_1/2(q^{m_1} - 1)} & \text{if } \ell_0 = \ell_1 < e/2 \text{ and } e \text{ is even}, \\
q^{m(e/2-1-\ell_0)+m_1/2(q^{m_0} - 1)} & \text{if } \ell_0 \neq \ell_1 \text{ and } e \text{ is even}, \\
q^{m(e-1)/2-\ell_0)+m_0/2(q^{m_1} - 1)} & \text{if } \ell_0 = \ell_1 \text{ and } e \text{ is odd}, \\
q^{m_0/2 - 1} & \text{if } \ell_0 \neq \ell_1, \ell_0 = (e-1)/2 \text{ and } e \text{ is odd}, \\
q^{m(e-1)/2-\ell_0)-m_0/2(q^{m_0} - 1)} & \text{if } \ell_0 \neq \ell_1, \ell_0 < (e-1)/2 \text{ and } e \text{ is odd}. \end{cases}
\]
4.5 Local factors of square-free hermitian lattices over ramified dyadic field extensions

Proof. Let \( u_0 \) be as in Corollary 3.3.17. If \((V, \Phi)\) is hyperbolic, let \( u = 0 \); otherwise let \( u = -u_0 \). For \( 0 \leq r \leq \frac{m}{2} \), let \( L_{k,r} \) and \( M_{k,r} \) be \( \mathcal{O}_p \)-lattices in \( (V_\ell, \Phi) \) such that

\[
L_{k,r} \cong \left\{ \left( \frac{1}{u_{p^{-k}}} \right) \right\} \perp H(0)^r \perp H(1)^s \quad \text{with} \quad 0 \leq k \leq \left\lfloor \frac{r}{2} \right\rfloor \quad \text{if} \quad u = 0,
\]

\[
M_{k,r} \cong \left\{ \left( \frac{1}{u_{p^{-k}}} \right) \right\} \perp H(0)^r \perp H(1)^s \quad \text{with} \quad 1 \leq k \leq \left\lfloor \frac{r + 1}{2} \right\rfloor \quad \text{if} \quad u = 0,
\]

\[
\left( \frac{1}{u_{p^{-k}}} \right) \quad \text{if} \quad u \neq 0,
\]

(4.5.3)

where \( s = \frac{m}{2} - r - 1 \). Note that, if \( \ell_0 \neq \ell_1 \), then \( L \cong L_{\ell_0, \frac{m}{2} - 1} \). Conversely, if \( \ell_0 = \ell_1 \), then \( L \cong M_{\ell_1, \frac{m}{2}} \).

First, the following claim will be established:

\[
\#D(L_{k,r}, M_{k+1,r}) = \begin{cases} 
q^r(q^{r+1} - 1) & \text{if} \quad k = \frac{r}{2}, \\
1 & \text{otherwise.}
\end{cases}
\]

\[
\#U(L_{k,r}, M_{k+1,r}) = \begin{cases} 
q^s(q^{s+1} - 1) & \text{if} \quad k = \frac{r}{2} - 1 \text{ and } u = 0, \\
q^s(q^{s+1} + 1) & \text{if} \quad k = \frac{r}{2} - 1 \text{ and } u \neq 0, \\
(q - 1)^{-1}(q^{2s+2} - 1) & \text{if} \quad k = \frac{r}{2}, \\
q^{1+2s} & \text{otherwise.}
\end{cases}
\]

(4.5.4)

The quantities \( \#D(L_{k,r}, M_{k+1,r}) \) have already been worked out in Remark 4.3.4 and Corollary 4.5.4. Also, the first two cases of \( \#U(L_{k,r}, M_{k+1,r}) = \#D(M_{k+1,r}^\ast, L_{k,r}^\ast) \) follow from Corollary 4.5.4. So only the last two cases of \( \#U(L_{k,r}, M_{k+1,r}) \) need to be discussed.

Let \( M_{k+1,r} = \langle x, y \rangle \perp M_0 \perp M_1 \) where \( G(x, y) = \left( \frac{1}{u_{p^{-k}}} \right) \), \( M_0 \cong H(0)^r \) and \( M_1 \cong H(1)^s \). Every element of \( U(L_{k,r}, M_{k+1,r}) \) is of the form \( M_{k+1,r} + \mathfrak{P}^{-1}v \) where \( v = \alpha x + \beta y + v_0 + v_1 \) with \( \alpha, \beta \in \mathcal{O} \) and \( v_1 \in M_1 \). Comparing norms and scales shows that one may assume \( v_0 = 0 \). Further, \( k \neq \frac{r}{2} \) implies \( \alpha \notin \mathfrak{P} \). By Theorem 3.3.18, each such \( v \) yields a lattice in \( U(L_{k,r}, M_{k+1,r}) \).

Similarly, one shows that

\[
\#U(L_{k,r}, M_{k,r}) = \begin{cases} 
(q - 1)^{-1}(q^{s+1} - 1)(q^{s} + 1) & \text{if} \quad k = \frac{r}{2}, \\
1 & \text{otherwise.}
\end{cases}
\]

\[
\#D(L_{k,r}, M_{k,r}) = \begin{cases} 
q^r(q^{r+1} - 1) & \text{if} \quad u = 0 \text{ and } k = \frac{r}{2}, \\
q^r(q^{r+1} + 1) & \text{if} \quad u \neq 0 \text{ and } k = \frac{r}{2}, \\
(q - 1)^{-1}(q^{2r+2} - 1) & \text{if} \quad k = \frac{r}{2}, \\
q^{1+2r} & \text{otherwise.}
\end{cases}
\]

(4.5.5)

In particular, for any fixed \( r \), one can compare the local factors of any pair of lattices defined in equation (4.5.3). In the following, only the cases where \( e \) is even will be discussed. The cases where \( e \) is odd are proved similarly.
1. Since $e$ is assumed to be even, the lattice $L_{e/2,m/2-1} \cong H(0)^{m/2}$ is $\mathfrak{p}^{e/2}$-maximal and therefore $\lambda(L_{e/2,m/2-1}) = 1$. If $1 \leq r < m/2$, then equation (4.5.5) shows that

$$\lambda(L_{e/2,r-1}) = \lambda(M_{e/2,r}) = \lambda(L_{e/2,r}) \cdot \frac{q^{2r+2} - 1}{q^{m/2-r} - 1} \frac{q^{m/2-1} - 1}{(q^{m/2-r} - 1)(q^{m/2-r-1} + 1)}$$

and therefore

$$\lambda(H(0)^r \perp H(1)^{m/2-r}) = \lambda(L_{e/2,r-1}) = \prod_{i=r}^{m/2-1} \frac{q^{2i+2} - 1}{q^{m/2-i} - 1} \frac{q^{m/2-1} - 1}{(q^{m/2-i} - 1)(q^{m/2-i-1} + 1)}$$

$$= \frac{q^{m/2-r} + 1}{2} \cdot \left( \frac{m/2}{r} \right) q^2,$$

$$\lambda(H(1)^{m/2}) = \lambda(M_{e/2,0}) = \lambda(L_{e/2,0}) \cdot \frac{q^2 - 1}{q^{m/2} - 1} \frac{q^{m/2} - 1}{(q^{m/2} - 1)(q^{m/2-1} + 1)} = \frac{q^{m/2} + 1}{2}.$$

This proves part 1.

2. Suppose $k < e/2$. From equations (4.5.4) and (4.5.5) it follows that

$$\lambda(L_{k,r}) = \lambda(L_{k+1,r}) \cdot \begin{cases} \frac{(q^{2r+2} - 1)q^{m/2-1-r}}{q^{m/2-1-r+1}} & \text{if } k = \frac{e}{2} - 1, \\ q^m & \text{otherwise}. \end{cases}$$

Hence

$$\lambda(L_{k,r}) = q^{m(e/2-1-k)+m/2-1-r} \cdot \frac{q^{2r+2} - 1}{q^{m/2-1-r} + 1} \cdot \lambda(L_{e/2,r}).$$

Equation (4.5.5) also yields

$$\lambda(M_{k,r}) = \lambda(L_{k,r}) \cdot q^{1+2r} = q^{m(e/2-1-k)+m/2+r} \cdot \frac{q^{2r+2} - 1}{q^{m/2-1-r} + 1} \cdot \lambda(L_{e/2,r}).$$

Part 2. now follows immediately by plugging in the explicit value of $\lambda(L_{e/2,r})$ into the previous two equations.

3. The lattice $M_{e/2,m/2-1}$ is $\mathfrak{p}^{e/2}$-maximal and therefore $\lambda(M_{e/2,m/2-1}) = \frac{q^{m-1}}{2(q+1)}$.

Corollary 4.5.4 gives

$$\#U(M_{e/2,r+1}, M_{e/2,r}) = \#D(M_{e/2,r}, M_{e/2,r+1}) = \frac{(q^{m/2-r-1} - 1)(q^{m/2-r+1} + 1)}{q - 1}.$$  

Conversely, let $M_{e/2,r+1} = M_0 \perp M_{-1}$ where $M_0 \cong H(0)^{r+1}$ and $M_{-1}$ is $\mathfrak{p}^{-1}$-modular. The lattices in $U(M_{e/2,r}, M_{e/2,r+1})$ are precisely the lattices $M_{e/2,r+1} + \mathfrak{p}^{-1}v$ where $v$ denotes a primitive vector in $M_0$. Thus $\#D(M_{e/2,r+1}, M_{e/2,r}) = (q - 1)^{-1}(q^{2r+2} - 1)$.
4.5 Local factors of square-free hermitian lattices over ramified dyadic field extensions

Hence

\[ \lambda(M_{\ell/2,r}) = \lambda(M_{\ell/2,e/2-1}) \cdot \prod_{i=r}^{m/2-2} \frac{q^{2i+2} - 1}{(q^{m/2-i-1} - 1)(q^{m/2-i} + 1)} \]
\[ = \frac{q^{m/2-r} - 1}{2} \left( \frac{m/2}{r} \right) q^2. \]

\[ \lambda(L_{\ell/2-1,r}) = \lambda(M_{\ell/2,r}) \cdot q^{m/2-r-1}(q^{m/2-r} + 1) = q^{m/2-r-1}q^{2r+2} - 1 \left( \frac{m/2}{r+1} \right) q^2. \]

Finally, suppose \( 0 \leq k \leq \frac{e}{2} - 2 \). Equations (4.5.4) and (4.5.5) show that

\[ \lambda(L_{k,r}) = q^m \cdot \lambda(L_{k+1,r}) = q^{m(e/2-1-k)} \cdot L_{e/2-1,r}; \]
\[ \lambda(M_{k+1,r}) = q^{2r+1-m} \cdot \lambda(L_{k,r}) = q^{m(e/2-2-k)+2r+1} \cdot L_{e/2-1,r}. \]

This finishes the proof of part 3. \( \square \)
5 Kneser’s Neighbour method

Let $K$ be a number field and let $(V, \Phi)$ be a regular hermitian space over $E$.

In this chapter, an algorithm to compute representatives of the isometry classes in the genus of some given $O$-lattice in $(V, \Phi)$ will be presented. The algorithm is originally due to M. Kneser, who introduced it in [Kne57] for quadratic lattices over the integers. It has then been adopted for number fields by R. Scharlau & B. Hemkemeier [SH98], for hermitian forms by A. Schiemann [Sch98] using ideas of D. Hoffmann [Hof91], and for quaternionic hermitian forms by C. Bachoc [Bac95]. The exposition given here follows [Sch98] and provides a uniform approach which works in all three cases.

5.1 Strong approximation

If $E$ is commutative, some problems arise. In such a case, the orthogonal or unitary group of $(V, \Phi)$ does not have the strong approximation property. Luckily there exist finite-index subgroups which have that property. Depending on $\dim_K(E)$, the following notation will be assumed in this chapter.

The case $E = K$

Let $v \in V$ be anisotropic. The reflection along $\langle v \rangle$

$$\tau_v: V \to V, \quad w \mapsto w - 2\frac{\Phi(w, v)}{\Phi(v, v)} v$$

defines an isometry in $O(V, \Phi)$. Conversely, any isometry $\varphi \in O(V, \Phi)$ can be expressed as a finite product $\varphi = \tau_{v_1} \circ \ldots \circ \tau_{v_r}$ of reflections. Using Clifford algebras, one can show that $\prod_{i=1}^r Q_\Phi(v_i) \in K^*/(K^*)^2$ does not depend on the chosen factorization (c.f. [O’M73, 54:6]). Hence there exists a unique group homomorphism $\theta: O(V, \Phi) \to K^*/(K^*)^2$ such that $\theta(\tau_v) = Q_\Phi(v)(F^*)^2$ for all anisotropic vectors $v \in V$. The map $\theta$ is called the spinor norm of $(V, \Phi)$. In [Zas62], H. Zassenhaus gives an equivalent definition of spinor norms in terms of determinants. His characterization yields a different proof for the fact that the spinor norm is a well defined group homomorphism.

Definition 5.1.1 The special orthogonal group of $(V, \Phi)$ is the kernel

$$SO(V, \Phi) = \{ \sigma \in O(V, \Phi) : \det(\sigma) = +1 \}$$

of $\det: O(V, \Phi) \to \{ \pm 1 \}$. Further, let

$$S(V, \Phi) = \{ \sigma \in SO(V, \Phi) : \theta(\sigma) = +1 \}$$
be the kernel of $\theta$, when restricted to $SO(V, \Phi)$. Similarly, one defines $SO(V_p, \Phi)$ and $S(V_p, \Phi)$ for all $p \in \mathbb{P}(\mathcal{O})$.

Two $\mathcal{O}$-lattices $L$ and $M$ in $(V, \Phi)$ are said to be in the same spinor genus if there exists an isometry $\sigma \in \mathcal{O}(V, \Phi)$ such that $L_p = \sigma(\varphi_p(M_p))$ with $\varphi_p \in S(V_p, \Phi)$ for all $p \in \mathbb{P}(\mathcal{O})$. The spinor genus of $L$ will be denoted by $sgen(L)$.

The case that $E/K$ is a quadratic field extension

**Definition 5.1.2** The special unitary group of $(V, \Phi)$ is the kernel

$$S(V, \Phi) := \{\sigma \in U(V, \Phi) : \text{det}(\sigma) = +1\}$$

of $\text{det}: U(V, \Phi) \to \{\pm 1\}$. Similarly, one defines $S(V_p, \Phi)$ for all $p \in \mathbb{P}(\mathcal{O})$.

Two $\mathcal{O}$-lattices $L$ and $M$ in $(V, \Phi)$ are said to be in the same special genus if there exists an isometry $\sigma \in U(V, \Phi)$ such that $L_p = \sigma(\varphi_p(M_p))$ with $\varphi_p \in S(V_p, \Phi)$ for all $p \in \mathbb{P}(\mathcal{O})$. The special genus of $L$ will be denoted by $sgen(L)$.

The case that $E/K$ is a quaternion algebra

To be able to present the theory in a uniform way, set $S(V, \Phi) = U(V, \Phi)$ and let the special genus $sgen(L)$ of any $\mathcal{O}$-lattice $L$ in $(V, \Phi)$ be the usual genus $gen(L)$.

By Theorem 2.4.5, every genus is a disjoint union of finitely many spinor/special genera which in turn are disjoint unions of finitely many isometry classes. As promised before, the group $S(V, \Phi)$ usually does have the strong approximation property.

**Theorem 5.1.3 (Strong approximation)** Suppose $\text{dim}_K(V) \geq 3$. Let $S \subseteq \mathbb{P}(\mathcal{O})$ be a set of prime ideals of $\mathcal{O}$ and let $T \subseteq S$ be a finite subset. Suppose that there exists a place $v$ of $K$ not corresponding to an ideal in $S$, such that $(V_v, \Phi)$ is isotropic. Further, let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$ and for $p \in T$ fix some $\sigma_p \in S(V_p, \Phi)$. Then for every $k \in \mathbb{N}$ there exists some $\sigma \in S(V, \Phi)$ such that

$$(\sigma - \sigma_p)(L_p) \subseteq p^kL_p \quad \text{for all } p \in T \quad \text{and} \quad \sigma(L_p) = L_p \quad \text{for all } p \in S - T.$$

**Proof.** See for example the article of M. Kneser [Kne66].

**Corollary 5.1.4** Suppose $\text{dim}_K(V) \geq 3$ and let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$.

1. If $(V, \Phi)$ is indefinite, then $sgen(L) = \text{cls}(L)$.

2. If $(V, \Phi)$ is definite, let $p \in \mathbb{P}(\mathcal{O})$ such that $(V_p, \Phi)$ is isotropic. Then there exists some $M \in sgen(L)$ such that $M_q = L_q$ for all $q \in \mathbb{P}(\mathcal{O}) - \{p\}$.

**Proof.** Let $M \in sgen(L)$. There exist some $\sigma \in U(V, \Phi)$ such that for all $q \in \mathbb{P}(\mathcal{O})$ one has $M_q = \sigma(\tau_q(L_q))$ for some $\tau_q \in S(V_q, \Phi)$. Set $S = \mathbb{P}(\mathcal{O}) - \{p\}$. Let $T = \{q \in \mathbb{P}(\mathcal{O}) : M_q \neq \sigma(L_q)\}$ and fix some $k \in \mathbb{N}$ such that $q^{2k}L_q \subseteq \tau_q(L_q)$ for all $q \in T$. By strong approximation, there exists some $\varphi \in S(V, \Phi)$ such that $\varphi(L_q) = \tau_q(L_q)$ for all $q \in S$. Hence $M_q = \sigma(\varphi(L_q))$ for all $q \in S$. 

74
In particular, if $E$ is a quaternion algebra, then every genus in $(V, \Phi)$ has class number one whenever $(V, \Phi)$ is indefinite.

### 5.2 Neighbours of a lattice

Let $L$ be an $O$-lattice in $(V, \Phi)$ and let $p$ be a good prime ideal of $\mathfrak{O}$ such that $L_p$ is modular. Further, let $\mathfrak{P}$ be some maximal left ideal of $O$ that contains $p$. After rescaling $\Phi$, one can make the following assumptions:

- If $p$ is unramified in $E$, then $L_p$ is unimodular.
- If $p$ is ramified in $E$, then $L_p$ is either unimodular or $\mathfrak{P}^{-1}$-modular.
- $L_q$ is integral for all $q \in \mathfrak{P}(\mathfrak{O}) - \{p\}$.

**Definition 5.2.1** In the above situation, one defines:

1. An $O$-lattice $L'$ in $(V, \Phi)$ is a $\mathfrak{P}$-neighbour of $L$ if $L'_p$ is $\mathfrak{P}(L_p)$-modular and there exist $O$-module isomorphisms
   \[ L/(L \cap L') \cong O/\mathfrak{P} \quad \text{and} \quad L'/\mathfrak{P} 
   \]
2. a) If $L_p$ is unimodular, then $x \in L$ is said to be $\mathfrak{P}$-admissible, if $x \notin \mathfrak{P}L$ and $Q_\Phi(x) \in \mathfrak{P}\mathfrak{P}$. If this is the case, let
   \[ L^x_\mathfrak{P} := \{ y \in L ; \Phi(x, y) \in \mathfrak{P}\} \quad \text{and} \quad L_{x, \mathfrak{P}} := L^x_\mathfrak{P} + \mathfrak{P}^{-1}x. \]
   b) If $L_p$ is $\mathfrak{P}^{-1}$-modular, then $x \in L$ is said to be $\mathfrak{P}$-admissible, if $x \notin \mathfrak{P}L$ and $Q_\Phi(x) \in p$. If this is the case, let
   \[ L^x_\mathfrak{P} := \{ y \in L ; \Phi(x, y) \in O\} \quad \text{and} \quad L_{x, \mathfrak{P}} := L^x_\mathfrak{P} + \mathfrak{P}^{-1}x. \]

The lattice $L_{x, \mathfrak{P}}$ is called the $\mathfrak{P}$-neighbour of $L$ at $x$.

**Remark 5.2.2** Let $x \in L$ be $\mathfrak{P}$-admissible.

1. Let $M$ be a $\mathfrak{P}$-neighbour of $L$. Then $L_q = M_q$ for all $q \in \mathfrak{P}(\mathfrak{O}) - \{p\}$. Further, $L_p$ and $M_p$ are both $\mathfrak{P}(L_p)$-modular. Hence $M$ and $L$ are in the same genus.

2. By the same argument, $L$ and $L_{x, \mathfrak{P}}$ are in the same genus.

3. $\sigma(L_{x, \mathfrak{P}}) = L_{\sigma(x), \mathfrak{P}}$ for all $\sigma \in \text{Aut}(L)$.

**Lemma 5.2.3** Let $M \neq L$ be an $O$-lattice in $(V, \Phi)$ such that $L_q = M_q$ for all $q \notin \mathfrak{P}(\mathfrak{O})$ different from $p$. If $E$ is a quadratic extension of $K$ which is split at $p$, it is further assumed that $\overline{\mathfrak{P}}M \subseteq L$ for some $e \geq 1$. Then $\overline{\mathfrak{P}}M \cap L \not\subseteq \overline{\mathfrak{P}}L$.
Proof. Suppose first that \( \mathfrak{P} \) is a twosided \( \mathcal{O} \)-ideal. Then there exists a minimal \( e \geq 0 \) such that \( \mathfrak{P} M \subseteq L \). Note that \( e \geq 1 \) since \( L \neq M \). The minimality of \( e \) implies that \( \mathfrak{P} M \cap L \not\subseteq \mathfrak{P} L \).

Suppose now that \( \mathfrak{P} \) is not a twosided \( \mathcal{O} \)-ideal. Then \( E \) is a quaternion algebra which is unramified at \( p \). Further \( \mathfrak{A} := \{ \alpha \in E ; \alpha M \subseteq L \} \) is a proper, integral, twosided ideal of \( \mathcal{O} \). Hence \( \mathfrak{A} = \mathcal{O} p^e \) for some \( e \geq 1 \), c.f. \cite[Lemma 3.1]{KV10}. Assume that \( \mathfrak{P} M \cap L \not\subseteq \mathfrak{P} L \).

\[ \mathcal{O} p^e M \subseteq \mathfrak{P} M \cap L \subseteq \mathfrak{P} L \]

and therefore \( \mathfrak{P}^{-1} \mathcal{O} p^e \subseteq \mathfrak{A} = \mathcal{O} p^e \). But then \( \mathfrak{P}^{-1} \subseteq \mathcal{O} \) yields the desired contradiction. \( \Box \)

Note that if \( M \) is a \( \mathfrak{P} \)-neighbour of \( L \) and \( E_p/K_p \cong K_p \oplus K_p \) then \( M/(L \cap M) \cong \mathcal{O}/\mathfrak{P} \) shows that \( \mathfrak{P} M \subseteq L \). Hence \( M \) satisfies the conditions of the previous lemma.

**Proposition 5.2.4** The set of all \( \mathfrak{P} \)-neighbours of \( L \) is given by

\[ \{ L_x, \mathfrak{P} ; x \in L \text{ is } \mathfrak{P} \text{-admissible} \} . \]

**Proof.** Let \( x \in L \) be \( \mathfrak{P} \)-admissible. Then

\[ L_x, \mathfrak{P} / (L \cap L_x, \mathfrak{P}) \cong (L_x, \mathfrak{P} + L) / L = (\mathfrak{P}^{-1} x + L) / L \cong \mathfrak{P}^{-1} x / (L \cap \mathfrak{P}^{-1} x) \cong \mathfrak{P}^{-1} / \mathcal{O} . \]

If \( L_p \) is unimodular, the \( \mathcal{O} \)-module morphism

\[ L \rightarrow \mathcal{O}/\mathfrak{P}, \quad y \mapsto \Phi(y, x) + \mathfrak{P} \]

has kernel \( L \cap L_x, \mathfrak{P} = L_p^0 \) and is surjective since \( \mathcal{O}/\mathfrak{P} \) is a simple \( \mathcal{O} \)-module. Similarly, if \( L_p \) is \( \mathfrak{P}^{-1} \)-modular, then

\[ L \rightarrow \mathfrak{P}^{-1}/\mathcal{O} \cong \mathcal{O}/\mathfrak{P}, \quad y \mapsto \Phi(y, x) + \mathcal{O} \]

is surjective with kernel \( L \cap L_x, \mathfrak{P} = L_p^0 \). Thus \( L_x, \mathfrak{P} \) is a \( \mathfrak{P} \)-neighbour of \( L \) in any case.

Conversely, let \( M \) be any \( \mathfrak{P} \)-neighbour of \( L \). Lemma 5.2.3 shows that there exists some \( x \in (\mathfrak{P} M \cap L) - \mathfrak{P} L \). Then \( x \) is \( \mathfrak{P} \)-admissible. The claim is that \( M = L_x, \mathfrak{P} \).

First note that \( L \cap M \subseteq L_p^0 \) since \( M \) is modular. Further, \( L_p \) is also modular, so \( L_p^0 \subseteq L \). Since \( L/(L \cap M) \) is a simple \( \mathcal{O} \)-module it follows that \( L_p^0 = L \cap M \). Thus \( L_p^0 \subseteq M \) and therefore \( L_x, \mathfrak{P} \subseteq M \). But then \( L_x, \mathfrak{P} = M \) by modularity. \( \Box \)

**Proposition 5.2.5 (Kneser)** Let \( M \in \text{gen}(L) \) such that \( L_q = M_q \) for all \( q \in \mathfrak{P}(p) - \{ p \} \).

If \( E/K \) is a quadratic extension which is split at \( p \), it is further assumed that \( \mathfrak{P} M \subseteq L \) for some \( e \geq 1 \). Then there exists a sequence of \( \mathcal{O} \)-lattices \( L = L_0, L_1, \ldots, L_r = M \) such that \( L_i \) is a \( \mathfrak{P} \)-neighbour of \( L_{i-1} \) for all \( 1 \leq i \leq r \).

**Proof.** Let \( e \geq 0 \) such that \( [L/(L \cap M)]_0 = p^e \). There is nothing to show if \( e = 0 \), so suppose \( e \geq 1 \). By Lemma 5.2.3 there exists some \( x \in (\mathfrak{P} M \cap L) - \mathfrak{P} L \). Then \( x \) is \( \mathfrak{P} \)-admissible. Further, \( L_x, \mathfrak{P} \cap M \) properly contains \( L \cap M \) since \( \mathfrak{P}^{-1} x \subseteq M \) but \( \mathfrak{P}^{-1} x \not\subseteq L \). Thus \( [L/(L_x, \mathfrak{P} \cap M)]_0 = p^f \) for some \( f < e \). The result follows by induction on \( e \).

\( \Box \)
5.3 Computing the neighbours

**Definition 5.2.6** The set of all $\mathcal{O}$-lattices $M$ in $(V, \Phi)$ such that there exists some $\sigma \in \mathbf{U}(V, \Phi)$ and a sequence $L = L_0, L_1, \ldots, L_r = \sigma(M)$ where $L_i$ is a $\mathfrak{P}$-neighbour of $L_{i-1}$ will be denoted by $\mathcal{N}(L, \mathfrak{P})$.

**Proposition 5.2.7** The set $\mathcal{N}(L, \mathfrak{P})$ coincides with

$$\{ M \in \text{gen}(L) : \text{there exists } M' \in \text{cls}(M) \text{ such that } L_q = M_q' \text{ for all } q \in \mathbb{P}(\mathfrak{o}) - \{p\} \}.$$  

**Proof.** In view of Proposition 5.2.5, only the case that $E_p \cong K_p \oplus K_p$ requires proof. Let $M \in \mathcal{N}(L, \mathfrak{P})$. By loc. cit. it suffices to show that there exists some $M' \in \text{cls}(M)$ such that $P^e M' \subseteq L$ for some $e \geq 0$. There exists some $f \geq 0$ such that $(P^f M')^M \subseteq L$. Without loss of generality, $\mathfrak{P}^M$ is principal, say generated by $\alpha \in E^*$. But then $M' := \alpha \alpha^{-1} M \in \text{cls}(M)$ satisfies $(P^f M')^M = (P^f (\mathfrak{P}^{-1}))^M \subseteq L$. □

**Corollary 5.2.8** Suppose $\dim_K(V) \geq 3$. If $(V_p, \Phi)$ is isotropic, then

$$\text{sgen}(L) \subseteq \mathcal{N}(L, \mathfrak{P}).$$

**Proof.** This follows immediately from Proposition 5.2.7 and Corollary 5.1.4. □

Note that $(V_p, \Phi)$ is isotropic at almost all prime ideals $p$, c.f. Theorem 3.2.2 and Corollary 3.2.4 for details.

5.3 Computing the neighbours

The space $(V, \Phi)$, the lattice $L$ as well as the prime ideals $p$ and $\mathfrak{P}$ are as before. This section explains the neighbour algorithm to compute a system of representatives of the isometry classes in $\mathcal{N}(L, \mathfrak{P})$ whenever $(V, \Phi)$ is definite. Let $\mathcal{O}' = \mathcal{O} \cap \mathcal{O}_r(\mathfrak{P})$ be the intersection of the left and right orders of $\mathfrak{P}$. Then $L/\mathfrak{P}L$ is a vector space over the finite field $\mathcal{O}'/\mathfrak{P}$. For $x \in L - \mathfrak{P}L$, the class of $x + \mathfrak{P}L$ in the projective $\mathcal{O}'/\mathfrak{P}$-space $L/\mathfrak{P}L$ will be denoted by $[x]$. Note that $\mathcal{O}' = \mathcal{O}$ unless $E$ is a quaternion algebra which is unramified at $p$. In this special case, $\mathfrak{P}$ is a non-invertible twosided ideal of $\mathcal{O}'$ and $\mathcal{O}'/\mathfrak{P} \cong \mathfrak{o}/p$.

The first question one has to answer is: ‘Which projective classes yield $\mathfrak{P}$-neighbours of $L$ and if so, how many?’ The exposition below follows A. Schiemann [Sch98, Section 3] who discusses the case that $\dim_K(E) = 2$.

**Lemma 5.3.1** For $\mathfrak{P}$-admissible vectors $x, y \in L$, the following statements are equivalent:

1. $L_{x, \mathfrak{P}} = L_{y, \mathfrak{P}}$

2. $[x] = [y]$ and $\Phi(x, y) \in \mathfrak{P}_6(L)\mathfrak{P}$.

**Proof.** 1. $\Rightarrow$ 2. From

$$\mathfrak{P}^{-1} \Phi(x, y) \mathfrak{P}^{-1} = \Phi(\mathfrak{P}^{-1} x, \mathfrak{P}^{-1} y) \subseteq \Phi(L_{x, \mathfrak{P}}, L_{x, \mathfrak{P}})$$
it follows that $\Phi(x, y) \in P(B(L))$ and
\[ \overline{\mathbb{P}L_x} + O_r(\mathbb{P})x = \overline{\mathbb{P}L_xL_y} = \overline{\mathbb{P}L_y} + O_r(\mathbb{P})y \]
\[ \subset \mathbb{P}L \]
shows that $y \equiv \alpha x \pmod{\mathbb{P}L}$ for some $\alpha \in O_r(\mathbb{P})$. It remains to show that $\alpha \in O$. Thus one may assume that $E$ is a quaternion algebra which is unramified at $p$. Since $O$ and $O_r(\mathbb{P})$ agree at all places of $K$ different from $p$, it suffices to show that $\alpha \in O_p$. Without loss of generality, $O_p = \mathbb{Z}_p^{2 \times 2}$ and $\mathbb{P} = O_p \cdot \left( \begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix} \right)$ where $p$ denotes some uniformizer of $p$.

Then $O_r(\mathbb{P})_p = \left( \begin{smallmatrix} a_p & 0 \\ 0 & a_p \end{smallmatrix} \right)$ and $\alpha = \left( \begin{smallmatrix} a & p \delta \\ p^{-1}c & d \end{smallmatrix} \right)$ for some $a, b, c, d \in \mathbb{O}_p$. Suppose $c \notin p\mathbb{O}_p$.

Let $(b_1, \ldots , b_m)$ be any $O_p$-basis of $L_p$. Then $x = \sum_{i=1}^m \lambda_i b_i$ for some $\lambda_i = \left( \begin{smallmatrix} a_i & b_i \\ c_i & d_i \end{smallmatrix} \right) \in O_p$.

The condition $\alpha x \in L$ shows that $\alpha \lambda_i \in O_p$ for all $i$. This is equivalent to $a_i, b_i \in p$, i.e. $\lambda_i \in \mathbb{P}p$. But this contradicts the assumption $x \notin \mathbb{P}L$. Hence $c \in p\mathbb{O}_p$ and therefore $\alpha \in O$.

2. $\rightarrow 1$. If $L_p$ is unimodular, let $\mathfrak{A} = \mathbb{P}$, otherwise let $\mathfrak{A} = O$. There exist $\alpha, \beta \in O' - \mathbb{P}$ and $v, w \in L_p$ such that $x = \alpha y + v$ and $y = \beta x + w$. Let $\gamma x + z \in L_{x,y}$ where $\gamma \in \mathbb{P}^{-1}$ and $z \in L_{p}$. To show that $\gamma x + z = \gamma \alpha y + \gamma v + z \in L_{y,\mathbb{P}}$, it suffices to show that $\gamma v + z \in L_{p}$.

\[ \Phi(y, \gamma v + z) \equiv \Phi(\alpha x, \gamma v + z) \equiv \Phi(\beta x, \gamma v) \equiv \beta \Phi(x, x - \alpha y) \equiv 0 \pmod{\mathfrak{A}}. \]

Hence $L_{x,y} \subseteq L_{y,\mathbb{P}}$. The converse inclusion follows the same way. $\square$

Using the previous result, one can write down minimal subsets $R(L, \mathbb{P}) \subset L$ such that \{ $L_{x,y} \mid x \in R(L, \mathbb{P})$ \} are the $\mathbb{P}$-neighbours of $L$. This generalizes [Sch98, Section 3].

**Proposition 5.3.2** Let $S$ be a system of representatives of the projective $O'/\mathbb{P}$-space $L/\mathbb{P}L$. Define a subset $R(L, \mathbb{P}) \subset L$ as follows:

1. If $E = K$, fix some $p \in \mathfrak{p} - \mathfrak{p}^2$. For any $x \in S$ with $Q_\Phi(x) \in \mathfrak{p}$, there exists some $z_x \in L$ such that $\Phi(z_x, x) \notin \mathfrak{p}$. Set
\[ R(L, \mathbb{P}) := \{ x + pb_xz_x \mid x \in S, Q_\Phi(x) \in \mathfrak{p} \} \]
where $b_x \in \mathfrak{a}$ such that $b_x \equiv -\frac{Q_\Phi(x)}{Q_\Phi(z_x, x)} \pmod{\mathfrak{p}}$.

2. If $E_p \cong K_p \oplus K_p$, set $R(L, \mathbb{P}) := \{ \pi x \mid x \in S \}$ where $\pi \in \mathbb{P} - \mathbb{P}$.

3. If $E_p \cong K_p^{2 \times 2}$, let $\pi \in \mathbb{P} - \mathbb{P}$. For any $x \in S$, there exist some $z_x \in L$ such that $\Phi(z_x, \pi x) \notin \mathbb{P}$. Further, there exists some $\beta_x \in pO$ such that $\beta_x \Phi(z_x, \pi x) \notin \mathbb{P}$. Set
\[ R(L, \mathbb{P}) := \{ \pi x + b\beta_xz_x \mid x \in S, b + p \in \mathfrak{p}/\mathfrak{p} \}. \]
Then \( \{ \beta z \in L \mid \beta \in \mathbb{P}, \Phi(\beta z, x) \in \mathfrak{O} \} \) are the \( \mathbb{P} \)-neighbours of \( L \) and no proper subset of \( R(L, \mathbb{P}) \) has this property.

**Proof.** 1. Let \( x \in L - pL \). Then \( Q_\Phi(x) \equiv Q_\Phi(y) \pmod{p} \) for all \( y + pL \in [x] \). Hence the projective lines \([x]\) with \( Q_\Phi(x) \notin p \) never yield \( p \)-neighbours. If \( Q_\Phi(x) \in p \), then \( z_x \) exists since \( L_p \) is unimodular. Further \( x + p\lambda_x z_x \) is \( p \)-admissible. So after replacing \( x \) with \( x + p\lambda_x z_x \), one may suppose that \( x \) is \( p \)-admissible. Let \( y \in L \) with \([x] = [y]\) also be \( p \)-admissible. Then \( y = ax + bz \) for some \( a \in \mathfrak{O} - p, b \in p \) and \( z \in L \). Thus
\[
Q_\Phi(y) = a^2 Q_\Phi(x) + 2ab \Phi(x, z) + b^2 Q_\Phi(z) \in p^2
\]
and therefore \( \Phi(x, y) \equiv b\Phi(x, z) \equiv 0 \pmod{p^2} \). Hence Lemma 5.3.1 shows that \([x]\) yields a single neighbour.

2. and 3. Let \( x \in L - \mathbb{P}L \). Then \( Q_\Phi(\pi x) \in \mathbb{P}\mathfrak{P} \). Note that this implies that \( \pi x \notin \mathbb{P}L \). This is clearly true if \( E \) is commutative and in the quaternion case one can argue as in the proof of Lemma 5.3.1. Hence \( R(L, \mathbb{P}) \) contains only \( \mathbb{P} \)-admissible vectors. Let \( y = \alpha \pi x + \beta z \) be \( \mathbb{P} \)-admissible where \( \alpha \in \mathfrak{O}' - \mathbb{P}, \beta \in \mathbb{P} \) and \( z \in L \). Then
\[
\Phi(y) = \sum_{\pi \in \mathbb{P}} \Phi(x) = \sum_{\pi \in \mathbb{P}} \Phi(x, z) + \sum_{\pi \in \mathbb{P}} \beta \Phi(z, x) = \sum_{\pi \in \mathbb{P}} \beta \Phi(z, x)
\]
shows that \( \beta \Phi(z, x) \pi \notin \mathbb{P} \). From \( \beta \Phi(z, x) \pi \notin \mathbb{P} \subseteq \mathfrak{O}' \) and \( \pi \notin \mathbb{P} \) it follows that \( \beta \Phi(z, x) \pi \notin \mathbb{P} \cap \mathfrak{O}' \). If \( E \) is commutative, then \( \mathbb{P} \cap \mathfrak{O}' = \mathbb{P} \mathfrak{P} \) and therefore \( \Phi(y, x) \equiv \beta \Phi(z, x) \equiv 0 \pmod{\mathbb{P} \mathfrak{P}} \). So by Lemma 5.3.1, the line \([x]\) only yields a single neighbour. This finishes the proof of part 2.

Suppose now \( E \) is a quaternion algebra. The element \( z_x \) exists since \( \pi x \notin \mathbb{P}L \) and \( L \) is unimodular. To show that \( \beta_x \) exists, one may suppose that \( \mathfrak{O}_p = \mathfrak{O}_p \mathfrak{P} \) and \( \mathbb{P} = \mathfrak{O}_p \cdot \left( \frac{1}{0} \right) \) where \( p \) denotes some uniformiser of \( p \). Then \( \Phi(z_x, \pi x) = \left( \frac{a}{b} \right) \) with \( a, b, c, \in \mathfrak{O}_p \). Set \( \beta_x = p \left( \frac{e f}{g h} \right) \) with \( e, f, g, h \in \mathfrak{O}_p \). Then \( \beta_x \Phi(z_x, \pi x) \in (\mathbb{P} \mathfrak{P})_p \) if and only if \( eb + hd \in p \).
The condition $\Phi(z_x, \pi x) \notin \mathfrak{P}$ implies that $b$ and $d$ cannot both lie in $p$. Hence there exists $\beta_2 \in \mathfrak{P}$ such that $\beta_2 \Phi(z_x, \pi x) \notin \mathfrak{P}$ and $\gamma \in \mathfrak{P}$. Let $y' = \alpha' \pi x + \beta' z'$ be $\mathfrak{P}$-admissible where $\alpha' \in \mathcal{O}' - \mathfrak{P}$, $\beta' \in \mathfrak{P}$ and $z' \in \mathfrak{L}$. By Lemma 5.3.1,

$$L_{y', \mathfrak{P}} = L_{y', \mathfrak{P}} \iff \beta \Phi(z, \pi x)\overline{\alpha} + \alpha \Phi(\pi x, z')\overline{\beta} \in \mathfrak{P}.$$ 

Since $(\mathfrak{P} \cap \overline{\mathfrak{P}})/\overline{\mathfrak{P}}$ is an one-dimensional $\mathfrak{o}/p$-space, the line $[x]$ gives rise to no more than $\#(\mathfrak{o}/p)$ neighbours. Conversely, the set $\{\pi x + b\beta_xz_x; b \in \mathfrak{o}/p\}$ yields $\#(\mathfrak{o}/p)$ different neighbours.

4. If $x \in \mathfrak{L} - \mathfrak{P} L$ and $Q_{\Phi}(x) \in \mathfrak{P}$ then $Q_{\Phi}(y) \in \mathfrak{P}$ for all $y + \mathfrak{P} L \in [x]$. Hence one only has to consider the projective lines $[x]$ such that $Q_{\Phi}(x) \in \mathfrak{P}$ and then every representative of $[x]$ is $\mathfrak{P}$-admissible. The existence of $z_x$ follows from the fact that $L$ is unimodular and $x \notin \mathfrak{P} L$. Suppose now $y = \alpha x + \beta z$ for some $\alpha \in \mathcal{O} - \mathfrak{P}$, $\beta \in \mathfrak{P}$ and $z \in \mathfrak{L}$. By Lemma 5.3.1, $x$ and $y$ yield the same neighbour if and only if $\beta \Phi(z, x) \in \mathfrak{P}^2$. Since $\beta \in \mathfrak{P}$, the line $[x]$ can yield no more than $\#(\mathcal{O}/\mathfrak{P})$ different neighbours. Conversely, different vectors from $\{x + \beta z_x; \beta + \mathfrak{P}^2 \in \mathfrak{P}^2\}$ never give the same neighbours.

5. A vector $x + \beta z_x$ with $\beta \in \mathfrak{P}$ is $\mathfrak{P}$-admissible if and only if $Q_{\Phi}(x) + T(\beta \Phi(z_x, x)) \in \mathfrak{P}$. Let $x' := x + \beta z_x$ and $y = \alpha x' + \gamma z$ with $\alpha \in \mathcal{O} - \mathfrak{P}$, $\beta \in \mathfrak{P}$ and $z \in \mathfrak{L}$ be $\mathfrak{P}$-admissible. After rescaling $y$ with some element in $\mathcal{O} - \mathfrak{P}$, one may assume that $\alpha = 1$. The assumption that $y$ is $\mathfrak{P}$-admissible yields that $\Phi(y, y) \equiv T(\gamma \Phi(z, x')) \equiv 0 \ (\text{mod } p)$. By Lemma 5.3.1, $x'$ and $y$ yield the same neighbour if and only if $0 \equiv \Phi(y, x') \equiv \gamma \Phi(z, x') \ (\text{mod } \mathfrak{P})$. Now the relative field extension $(\mathcal{O}/\mathfrak{P})/(\mathfrak{o}/p)$ is either trivial or quadratic, depending on $\dim_{K}(E)$. So $[x]$ yields a single neighbour if $E$ is commutative but $\#(\mathfrak{o}/p)$ different neighbours if $E$ is a quaternion algebra. Conversely, the set

$$\{x + \beta z_x; \beta + \mathfrak{P}^2 \in \mathfrak{P}^2 \text{ and } Q_{\Phi}(x) + T(\Phi(\beta z_x, x)) \in \mathfrak{P}\}$$

consists of $\mathfrak{P}$-admissible representatives of $[x]$ that yield the correct number of neighbours.

6. If $x \in \mathfrak{L} - \mathfrak{P} L$ such that $Q_{\Phi}(x) \notin \mathfrak{P}$, then $[x]$ contains no admissible vector. Suppose now $x \in \mathfrak{L} - \mathfrak{P} L$ and $Q_{\Phi}(x) \in \mathfrak{P}$. Let $y = \alpha x + p\beta z$ with $\alpha \in \mathcal{O} - \mathfrak{P}$, $\beta \in \mathcal{O}$ and $z \in \mathfrak{L}$ by any representative of $[x]$. If $y$ is $\mathfrak{P}$-admissible, so is $\gamma y$ and the two vectors give the same neighbour. Hence one may assume that $\alpha = 1$. Then $y$ is $\mathfrak{P}$-admissible if and only if $Q_{\Phi}(x)/p + T(\beta \Phi(y, x)) \in \mathfrak{P}$. If $\Phi(y, x) \in \mathfrak{P}$ and $y$ is $\mathfrak{P}$-admissible, then $x$ is $\mathfrak{P}$-admissible and $L_{x, \mathfrak{P}} = L_{y, \mathfrak{P}}$. Suppose $\Phi(y, x) \notin \mathfrak{P}$. The trace bilinear form of the relative extension $(\mathcal{O}/\mathfrak{P})/(\mathfrak{o}/p)$ is non-degenerate, hence there are $\#(\mathfrak{o}/p)$ classes $\beta + \mathfrak{P} \in \mathcal{O}/\mathfrak{P}$ such that $y$ is $\mathfrak{P}$-admissible. From Lemma 5.3.1 it follows that the projective line $[x]$ yields no more than $\#(\mathfrak{o}/p)$ different neighbours. Conversely, the vectors in

$$\{x + p\beta z_x; \beta + \mathfrak{P} \in \mathcal{O}/\mathfrak{P} \text{ and } Q_{\Phi}(x)/p + T(\beta \Phi(z_x, x)) \in \mathfrak{P}\}$$

are $\mathfrak{P}$-admissible and they give rise to different neighbours.

Using the previous result, one can count the number of $\mathfrak{P}$-neighbours of $L$, see [Sch98, Lemma 3.3].
5.3 Computing the neighbours

Corollary 5.3.3  In the situation of Lemma 5.3.1 let \( q = \text{Nr}_{K/Q}(p) \) and \( s(L_p) = \mathfrak{P}^i \). The number \( #R(L, \mathfrak{P}) \) of \( \mathfrak{P} \)-neighbours of \( L \) is given by the following table:

<table>
<thead>
<tr>
<th>( \dim_K(E) )</th>
<th>( m )</th>
<th>( E_p/K_p )</th>
<th>( i )</th>
<th>( #R(L, \mathfrak{P}) )</th>
</tr>
</thead>
<tbody>
<tr>

<td>( q^2(q^m - (1)^m)/(q^2 - 1) )</td>
</tr>
</tbody>
</table>

where \( \varepsilon = +1 \) if \( \text{disc}(V, \Phi) \in \mathbb{N}(E_p^\times) \) and \( \varepsilon = -1 \) otherwise.

Proof. If \( E = K \), one may assume that \( i = 0 \). Then \( #R(L, \mathfrak{P}) \) is the number of isotropic lines in the \( \mathfrak{o}/p \)-space \( L' := L/\mathfrak{P}L \) equipped with the quadratic form

\[ Q': L' \to \mathfrak{o}/p, \ x + \mathfrak{P}L \mapsto Q_{\Phi}(x) + p . \]

These numbers have been worked out for example in [Kne02, Section V.13]. Suppose \( \dim_K(E) = 2 \). The split case as well as the ramified case with \( i \) odd are obvious. In the remaining cases, one may assume that \( i = 0 \) and again, it boils down to work out the number of isotropic lines in \( (L', Q') \). Note that if \( p \) is inert in \( E \), then \( (L', Q') \) is of dimension \( 2m \) and hyperbolic if and only if \( m \) is even, see [Sch98, Lemma 3.3] for details. Suppose now \( \dim_K(E) = 4 \). If \( p \) is ramified in \( E \) and \( i \) is even, one may assume that \( i = 0 \). Then \( #R(L, \mathfrak{P})(q^3 - 1)/q^2 \) is the number of anisotropic vectors in the \( 2m \)-dimensional \( \mathfrak{o}/p \)-space \( L' := L/\mathfrak{P}L \) equipped with the quadratic form

\[ Q': L' \to \mathfrak{o}/p, \ x + \mathfrak{P}L \mapsto Q_{\Phi}(x) + p . \]

The quadratic space \( (L', Q') \) is again hyperbolic if and only if \( m \) is even. All other cases are again trivial.

Lemma 5.3.1 yields a method to enumerate the set of all isometry classes in \( \mathcal{N}(L, \mathfrak{P}) \) which are represented by \( \mathcal{N}(L, \mathfrak{P}) \).

Algorithm 5.3.4 IteratedNeighbours\((L, \mathfrak{P})\)

Input: An \( \mathcal{O} \)-lattice \( L \) in a definite hermitian space \( (V, \Phi) \) over \( E \) of dimension \( m \) and some maximal left ideal \( \mathfrak{P} \) of \( \mathcal{O} \) such that \( p := \mathfrak{P} \cap \mathfrak{o} \) satisfies the assumptions made in the beginning of Section 5.2.

Output: A set \( S \) of representatives of the isometry classes in \( \mathcal{N}(L, \mathfrak{P}) \).

1: If \( L_p \) is unimodular, set \( \mathfrak{A} = \mathfrak{P} \); otherwise set \( \mathfrak{A} = \mathcal{O} \).
2: Initialise the sets \( S = T = \{ L \} \).
3: \textbf{while} there exists some \( M \in T \) \textbf{do}
4: \hspace{1em} Exclude \( M \) from \( T \).
5: \hspace{1em} Let \((x_1, \ldots, x_m)\) be a basis of a free \( O \)-submodule \( M' \) of \( M \) such that \( M_p = \overline{M_p} \).
6: \hspace{1em} for \( x \in R(M, \mathfrak{P}) \) \textbf{do}
7: \hspace{2em} Set \( I := \{ 1 \leq i \leq m \; ; \; \Phi(x, x_i) \notin \mathfrak{A} \} \) and \( i := \min(I) \).
8: \hspace{2em} For \( j \in I - \{ i \} \) let \( \lambda_j \in O \) such that \( \Phi(x, x_j) - \Phi(x, x_i) \overline{\lambda_j} \in \mathfrak{A} \).
9: \hspace{2em} Set \( L' := \sum_{j \notin I} \mathcal{O} x_j + \sum_{j \in I - \{ i \}} \mathcal{O} (x_j - \lambda_j x_i) + \overline{\mathfrak{A}} x_i + \overline{\mathfrak{P}}^{-1} x + pM. \)
10: \hspace{2em} if \( L' \) is not isometric to any element in \( S \) then
11: \hspace{3em} Include \( L' \) to both \( S \) and \( T \).
12: \hspace{1em} end if
13: \hspace{1em} end for
14: \hspace{1em} end while
15: \hspace{1em} return \( S \).

\textit{Proof.} Note that by induction, the lattice \( M \) is always modular at \( p \). Hence \( I \) is nonempty. Further, the lattice \( L' \) in line 9 equals \( M_x, \mathfrak{P} \). So the algorithm does enumerate some lattices in \( \mathcal{N}(L, \mathfrak{P}) \). The algorithm terminates since the number of isometry classes in \( \text{gen}(L) \) is finite. The fact that the algorithm reaches every isometry class in \( \mathcal{N}(L, \mathfrak{P}) \) follows from Proposition 5.2.5 and Remark 5.2.2. \( \square \)

### 5.4 Enumerating all isometry classes in a given genus

In this section, algorithms to compute a system of representatives of all isometry classes of an \( O \)-lattice \( L \) in \((V, \Phi)\) are given. In view of Corollary 5.1.4 and Algorithm 5.3.4, it suffices to answer the question, which spinor/special genera have to be joined to cover a given genus completely. If \( E \) is a quaternion algebra, then \( \text{gen}(L) = \text{sgen}(L) \). So only the two cases where \( E \) is commutative remain. They will be discussed individually below.

#### 5.4.1 The quadratic case

Suppose \( E = K \) is a number field and let \((V, \Phi)\) be a regular quadratic space over \( K \) of rank \( m \geq 3 \). The question how the genus of some lattice decomposes into spinor genera is answered by M. Kneser in [Kne56] using the spinor norms introduced by M. Eichler. It turns out that a description using proper isometry classes is more suitable.

\textbf{Definition 5.4.1} Let \( L, L' \) be \( o \)-lattices in \((V, \Phi)\).

1. The lattices \( L \) and \( L' \) are said to be \textit{properly isometric}, if \( L' = \varphi(L) \) for some \( \varphi \in \text{SO}(V, \Phi) \). The \textit{proper isometry class} \( \text{cls}^+(L) \) is the set of all \( o \)-lattices properly isometric to \( L \) and \( \text{Aut}^+(L) := \text{Aut}(L) \cap \text{SO}(V, \Phi) \) is the \textit{proper automorphism group} of \( L \). Similarly one defines \( \text{Aut}^+(L_p) \) for \( p \in \mathbb{P}(o) \).

2. The lattices \( L \) and \( L' \) are said to be in the same \textit{proper spinor genus}, if there exists some \( \varphi \in \text{SO}(V, \Phi) \) such that \( \varphi(L)_p = \sigma_p(L'_p) \) with \( \sigma_p \in \mathcal{S}(V_p, \Phi) \) for all \( p \in \mathbb{P}(o) \). The proper spinor genus of \( L \) will be denoted by \( \text{sgen}^+(L) \).
5.4 Enumerating all isometry classes in a given genus

The following remark explains how classes, spinor genera and genera differ from their ‘proper’ counterparts, see also Corollary 5.4.8.

Remark 5.4.2 Let $L$ be an $\mathfrak{o}$-lattice in $(V, \Phi)$ and let $p \in \mathbb{P}(\mathfrak{o})$.

1. $\text{cls}(L) = \text{cls}^+(L)$ if and only if $\text{Aut}(L) \neq \text{Aut}^+(L)$. In particular, if $m$ is odd, then $-\text{id}_V \in \text{Aut}(L) - \text{Aut}^+(L)$, so $\text{cls}(L) = \text{cls}^+(L)$.

2. If $\text{Aut}(L) = \text{Aut}^+(L)$, then $\text{cls}(L) = \text{cls}^+(L) \cup \text{cls}^+(\tau(L))$ where $\tau$ denotes any isometry in $\text{SO}(V, \Phi) - \text{SO}(V, \Phi)$. For example one can take $\tau$ to be a reflection.

3. Let $x \in L_p$ such that $Q_\Phi(x) \mathfrak{o} = n(L_p)$. The reflection $\tau_x$ fixes $L$. In particular, $[\text{Aut}(L_p) : \text{Aut}^+(L_p)] = 2$. Moreover, if $L' \in \text{gen}(L)$, then for all $p \in \mathbb{P}(\mathfrak{o})$ there exists some $\sigma_p \in \text{SO}(V_p, \Phi)$ such that $L_p = \sigma_p(L'_p)$.

For the remainder of this section let $L$ be a fixed $\mathfrak{o}$-lattice in $(V, \Phi)$.

Definition 5.4.3 Given a prime ideal $p$ of $\mathfrak{o}$, the group of spinor norms of $L_p$ is

$$\theta(L_p) := \theta(\text{Aut}^+(L_p)) = \{\theta(\sigma) : \sigma \in \text{Aut}^+(L)\}.$$

For odd prime ideals, the computation of spinor norms was also solved by M. Kneser.

Theorem 5.4.4 Suppose $p \in \mathbb{P}(\mathfrak{o})$ is odd. Let $L_p = \bigcup_{i=1}^r L_i$ be a Jordan decomposition and let

$$F = \bigcup_{1 \leq i \leq r} \{Q_\Phi(x) : x \in L_i \text{ and } Q_\Phi(x) \notin p\mathfrak{s}(L_i)\}.$$

Then $\theta(L_p) = \{(\prod_{i=1}^{2\ell} f_i)(K_p^*)^2 : f_i \in F \text{ and } \ell \in \mathbb{N}\}$. In particular, $\mathfrak{o}_p^*(K_p^*)^2 \subseteq \theta(L_p)$ if rank$(L_i) > 1$ for some $i$ and $\theta(L_p) = \mathfrak{o}_p^*(K_p^*)^2$ if $L$ is modular.

Proof. See [Kne56, Satz 3].

If $p$ is a prime ideal over 2, then $\mathfrak{o}_p^*(K_p^*)^2 \subseteq \theta(L_p)$ if $L_p$ has a Jordan block of rank at least 3, c.f. [O’M73, Example 93:20]. The explicit computation of $\theta(L_p)$ is quite involved and was only solved recently by C. Beli in [Bel03].

The question, whether $M \in \text{gen}(L)$ is in the same proper spinor genus as $L$ can be answered using idèles. The presentation given here follows T. O’Meara [O’M73, Section 102]. For the remainder of this section, the following notation will be used.

- The group of idèles of $K$ will be denoted by

$$J = \{(x_v)_v \in \prod_{v \in \Omega(K)} K_v^* : x_p \in \mathfrak{o}_p^* \text{ for all but finitely many } p \in \mathbb{P}(\mathfrak{o})\}.$$

Note that $K^*$ can be regarded as a subgroup of $J$ via the diagonal embedding.

- Given a prime ideal $p$ of $\mathfrak{o}$ and some $x \in K_p^*$, let $j(p, x)$ be the idèle satisfying $j(p, x)_p = x$ and $j(p, x)_v = 1$ for all places $v$ different from $p$.

83
Each $\mathcal{P}$ isometry class of $\text{gen}(\mathcal{L})$ isomorphism between $\mathcal{L}$ to cover all isometry classes of $\text{gen}(\mathcal{L})$. So the above theorem tells exactly, which (proper) spinor genera have to be joined in places $\nu_L$. Theorem 5.4.5

Let $\mathcal{M} \in \text{gen}(\mathcal{L})$. Define some idèle $j \in \mathcal{J}$ as follows. If $p \in \mathcal{P}(\mathcal{O})$ with $L_p \neq M_p$ set $j_p = \theta(\sigma_p)$ where $\sigma_p \in \text{SO}(V_p, \Phi)$ such that $M_p = \sigma_p(L_p)$. On all other places $v$ of $K$ set $j_v = 1$. Then $\mathcal{M} \in \text{sgen}^{+}(\mathcal{L})$ if and only if $j \in K_S^*J_L$. In particular, the number of proper spinor genera in $\text{gen}(\mathcal{L})$ is $|J: K_S^*J_L| < \infty$.

Proof. See for example [O'M73, Section 102].

So the above theorem tells exactly, which (proper) spinor genera have to be joined in order to cover all isometry classes of $\text{gen}(\mathcal{L})$. However, the group $J/K_S^*J_L$, being a quotient of two infinite groups, is difficult to handle algorithmically. Thus an explicit isomorphism between $J/K_S^*J_L$ and some quotient of the ray class group $\text{Cl}_D(\mathcal{O})$ will be given below. I learned this description from Wai Kiu Chan [Cha13] on the AIM conference on Algorithms for lattices and algebraic automorphic forms.

Theorem 5.4.6

1. The map $J/K^* \rightarrow J/K_S^*J_L$, $jK^* \mapsto cjK_S^*J_L$ with $c \in K^*$ such that $cj \in J_S$ is a well defined, surjective homomorphism of groups with kernel $K^*J_L^L/K^*$. Hence it induces an isomorphism

$$\psi_1 : J/K^*J_L^L \rightarrow J/K_S^*J_L.$$ 

2. The map $\psi : J/K^* \rightarrow \text{Cl}_D(\mathcal{O})$, $jK^* \mapsto [cj]$ where $c \in K^*$ such that $cj \in J_S$ and $c_j p \equiv 1 \pmod{p^{1+\text{ord}_{p}(4)}}$ for all $p \in P$ is a well defined, surjective homomorphism of groups with kernel $K^*J_D/K^*$. Hence it induces an isomorphism

$$\psi_2 : J/K^*J_D \rightarrow \text{Cl}_D(\mathcal{O}).$$

3. For $p \in P$ let $\mathcal{X}_p$ be a set of generators of $\theta(L_p)/(K_p^*)^2$. Then $U = \{\psi(j(p, x)K^*) : x(K_p^*)^2 \in \mathcal{X}_p, p \in P\}$, $\text{Cl}_D(\mathcal{O})^2$
does not depend the chosen representatives. Further,
\[ \phi: J/K^*JL \to \text{Cl}_D(\mathfrak{o})/U, \ jK^*JL \mapsto \psi(jK^*)U \]
is an isomorphism.

**Proof.** The first two parts are verified directly. The choice of \( D \) implies that \( J^2J_D \subseteq J^L_S \). Further, \( \psi \) maps \( K^*J^2J_D/K^* \) onto \( \text{Cl}_D(\mathfrak{o})^2 \). Since \( \text{Cl}_D(\mathfrak{o})/\text{Cl}_D(\mathfrak{o})^2 \) is an elementary abelian 2-group, the subgroup \( U \) does not depend on the sets \( X_p \). The elements in \( K^*J^L_S/K^*J^2J_D \) are generated by idèles of the form \( \{j(p,x) ; p \in P \text{ and } x \in X_p \} \). So the image of \( K^*J^L_S/K^*J_D \) under \( \psi_2 \) is \( U \). Thus \( \phi \) is an isomorphism. \( \square \)

Theorems 5.4.5 and 5.4.6 yield the following results, including an algorithm for computing representatives of the isometry classes in \( \text{gen}(L) \) in the definite case.

**Corollary 5.4.7** Let \( M \in \text{gen}(L) \) and let \( j \) be the idèle from Theorem 5.4.5. Then the following statements are equivalent:

1. \( M \in \text{sgen}^+(L) \).
2. \( j \in K^*J^L \).
3. \( \phi(j) = 1 \) where \( \phi \) is as in Theorem 5.4.6.

**Corollary 5.4.8** Let \( x \in V \) be anisotropic and let \( Q = \{ p \in \mathbb{P}(\mathfrak{o}) ; Q_\Phi(x)p \neq n(L)_p \} \). For \( p \in P \cup Q \) let \( x_p \in L_p \) such that \( Q_\Phi(x_p)p = n(L)_p \). Let \( j \in J \) be defined by
\[
j_v = \begin{cases} 1 & \text{if } v \notin P \cup Q, \\ Q_\Phi(x)Q_\Phi(x_v) & \text{if } v \in P \cup Q. \end{cases}
\]

Then the following statements are equivalent:

1. \( \text{sgen}^+(L) = \text{sgen}(L) \).
2. \( \text{sgen}^+(L') = \text{sgen}(L') \) for all \( L' \in \text{gen}(L) \).
3. \( \phi(j) = 1 \) where \( \phi \) is as in Theorem 5.4.6.

In particular, if these conditions hold, then the number of proper spinor genera in \( \text{gen}(L) \) equals the number of spinor genera in \( \text{gen}(L) \). Otherwise it is twice that number.

**Proof.** The equality \( \text{sgen}^+(L) = \text{sgen}(L) \) holds if and only if \( \tau_v(L) \in \text{sgen}^+(L) \). The latter condition is equivalent to \( \phi(j) = 1 \) by Theorems 5.4.5 and 5.4.6. Further, \( j \) only depends on \( \text{gen}(L) \) by construction. \( \square \)

In view of Proposition 5.2.7, let \( \mathcal{N}^+(L,p) \) be the set
\[
\{ M \in \text{gen}(L) ; \text{there exists } M' \in \text{cls}^+(M) \text{ such that } L_q = M'_q \text{ for all } q \in \mathbb{P}(\mathfrak{o}) \setminus \{p\} \}.
\]
The decomposition of \( \mathcal{N}^+(L,p) \) into proper spinor genera is explained by the following result which strengthens Corollary 5.2.8/3.
Lemma 5.4.9 Let $U$ be the subgroup of $\text{Cl}_D(\mathfrak{o})$ as in Theorem 5.4.6. Let $p \in \mathfrak{P}(\mathfrak{o})$ be odd such that $L_p$ is modular. Further, let $M$ be a $p$-neighbour of $L$ and let $p$ denote a uniformiser of $p$.

1. There exists some $\sigma \in \text{SO}(V_p, \Phi)$ such that $M_p = \sigma(L_p)$ and $\theta(\sigma) = p(K^*)^2$.

2. The set $N^+(L, p)$ consists of at most two proper spinor genera. More precisely, if $[p] \in U$, then $N^+(L, p) = \text{sgen}^+(L)$. Otherwise $N^+(L, p) = \text{sgen}^+(L) \cup \text{sgen}^+(M)$.

Proof. 1. There exists some $p$-admissible $x \in L$ such that $M = L_{x, p}$. Let $y \in L_p$ such that $\Phi(x, y) = 1$. In particular, $L_p = \langle x, y \rangle \perp L'$ for some suitable sublattice $L'$ of $L_p$. Then $M_p = \langle p^{-1}x, py \rangle \perp L'$. Hence it suffices to discuss the case that $\text{rank}(L) = 2$. After replacing $x$ with $x + upy$ for some $u \in \mathfrak{p}$, one may assume that $Q_\Phi(x) = 0$. So without loss of generality, the Gram matrix of $(x, y)$ is $H(0)$. But then $\sigma := \tau_{x-yp} \circ \tau_{x-y}$ does the trick. 2. This is an immediate consequence of the previous corollary and the first part. □

Corollary 5.4.10 Suppose $(V, \Phi)$ is indefinite. Let $\phi, U$ be as in Theorem 5.4.6 and let $j$ be as in Corollary 5.4.8. Then

1. $\text{sgen}(L) = \text{cls}(L)$ and $\text{sgen}^+(L) = \text{cls}^+(L)$. Moreover, $\text{cls}^+(L) = \text{cls}(L)$ if and only if $\phi(j) = 0$.

2. Let $[p_1], \ldots, [p_{h^+}]$ be odd prime ideals of $\mathfrak{o}$ such that $L_{p_i}$ is modular and $\{p_1, \ldots, p_{h^+}\}$ is a transversal of $U$ in $\text{Cl}_D(\mathfrak{o})$. Let $L_i$ be a $p_i$-neighbour of $L$. Then $L_1, \ldots, L_{h^+}$ represent the proper isometry classes (proper spinor genera) in $\text{gen}(L)$.

3. Let $[p_1], \ldots, [p_h]$ be odd prime ideals of $\mathfrak{o}$ such that $L_{p_i}$ is modular and $\{p_1, \ldots, p_h\}$ is a transversal of $(U, \phi(j))$ in $\text{Cl}_D(\mathfrak{o})$. Let $L_i$ be a $p_i$-neighbour of $L$. Then $L_1, \ldots, L_h$ represent the isometry classes (spinor genera) in $\text{gen}(L)$.

Proof. The first assertion is a consequence of strong approximation, c.f. Corollary 5.1.4 and the second follows immediately from Corollary 5.4.7 and Lemma 5.4.9. The last assertion follows from the first two parts and Corollary 5.4.8. □

So the above result solves the indefinite case. The definite case is handled by the following algorithm.

Algorithm 5.4.11 GenusRepresentatives($L$)

Input: An $\mathfrak{o}$-lattice $L$ in the definite quadratic space $(V, \Phi)$ over $K$.

Output: A set of representatives of the isometry classes in $\text{gen}(L)$.

1. Let $p \in \mathfrak{P}(\mathfrak{o})$ of minimal norm such that $2 \notin \mathfrak{p}$ and $L_p$ is modular.

2. Let $U$ be the subgroup of $\text{Cl}_D(\mathfrak{o})$ as in Theorem 5.4.6.

3. Replace $U$ by $\langle U, [p] \rangle \leq \text{Cl}_D(\mathfrak{o})$.

4. Compute a set $G$ of prime ideals, coprime to $2\mathfrak{o}$, such that $L_\mathfrak{q}$ is modular for all $\mathfrak{q} \in G$ and $\{[\mathfrak{g}]U : \mathfrak{g} \in G\}$ generates $\text{Cl}_D(\mathfrak{o})/U$. 86
5.4 Enumerating all isometry classes in a given genus

5: Let \( S \) be the output of \text{IteratedNeighbours}(L, p) and initialize the list \( S = [S] \).
6: Initialise \( i = 1 \).
7: \textbf{while} \( i \leq \# S \) \textbf{do}
8: \hspace{1em} \textbf{for} \( q \in G \) \textbf{do}
9: \hspace{2em} Let \( M \) be a \( q \)-neighbour of \( L' \) where \( L' \in S[i] \).
10: \hspace{2em} \textbf{if} there exists no lattice in \( \bigcup_{S \in S} S \) isometric to \( M \) \textbf{then}
11: \hspace{3em} Let \( S \) be the output of \text{IteratedNeighbours}(M, p).
12: \hspace{3em} Append \( S \) as the last element of \( S \).
13: \hspace{2em} \textbf{end if}
14: \hspace{1em} \textbf{end for}
15: \hspace{1em} Increment \( i \).
16: \hspace{1em} \textbf{end while}
17: \textbf{return} \( \bigcup_{S \in S} S \).

\textbf{Proof.} Theorems 5.4.5 and 5.4.6 show that the group \( \text{Cl}_D(\mathcal{O})/U \) acts transitively on the spinor genera in the genus of \( L \) via 
\[(|g|U, \text{sgen}(L')) \mapsto \text{sgen}(M') \text{ where } M' \text{ denotes some } g\text{-neighbour of } L'.\]

The algorithm simply implements the standard orbit enumeration of the orbit of \( \text{sgen}(L) \) under this action. Note that Algorithm 5.3.4 computes representatives of the isometry classes of one or two spinor genera. Hence the check in line 10 ensures that each spinor genus is only visited once. \( \square \)

5.4.2 The hermitian case

Suppose \( E/K \) is a quadratic extension of number fields. The question how the genus of a given \( \mathcal{O} \)-lattice \( L \) decomposes into special genera was answered by G. Shimura in [Shi64]. To state the result, some more notation is required.

- Let \( C_0 = \{[\mathfrak{A}] \in \text{Cl}(\mathcal{O}) ; \mathfrak{A} = \mathfrak{A} \} \triangleleft \text{Cl}(\mathcal{O}) \). The group \( C_0 \) is generated by
  \[\{[\mathfrak{P}] \in \text{Cl}(\mathcal{O}) ; \mathfrak{P} \text{ a ramified prime ideal of } \mathcal{O}\} \cup \{[a\mathcal{O}] \in \text{Cl}(\mathcal{O}) ; [a] \in \text{Cl}(\mathcal{O})\} \cdot\]

- Further, let \( J \) and \( J_0 \) be the subgroups of the group \( \mathcal{I}(\mathcal{O}) \) of fractional ideals of \( \mathcal{O} \) defined by
  \[J = \{\mathfrak{A} \in \mathcal{I}(\mathcal{O}) ; \mathfrak{A}\mathfrak{A} = \mathcal{O}\} \text{ and } J_0 = \{\alpha\mathcal{O} ; \alpha \in E^*; \alpha\overline{\alpha} = 1\} \trianglelefteq J.\]

- Given a prime ideal \( q \) of \( \mathcal{O} \), set
  \[\mathcal{E}_{q,0} = \{\varepsilon \in \mathcal{O}_q^* ; \varepsilon\overline{\varepsilon} = 1\},\]
  \[\mathcal{E}_{q,1} = \{\overline{\varepsilon}^{-1} ; \varepsilon \in \mathcal{O}_q^*\} \trianglelefteq \mathcal{E}_{q,0},\]
  \[\mathcal{E}(L_q) = \{\det(\sigma) ; \sigma \in \text{Aut}(L_q)\} \trianglelefteq \mathcal{E}_{q,0}.\]
Remark 5.4.12 Let $q$ be a prime ideal of $\mathfrak{o}$ that is ramified in $E$.

1. The homomorphism $C \to J/J_0$, $[\mathfrak{A}] \mapsto \mathfrak{A}\mathfrak{A}^{-1} \cdot J_0$ is well-defined and surjective with kernel $C_0$. In particular, $[C : C_0] = [J : J_0]$.

2. The homomorphism $E_q^* \to E_{q,0}/E_{q,1}$, $\alpha \mapsto \alpha\overline{\alpha}^{-1}E_{q,1}$ is surjective by Hilbert’s Theorem 90 and has kernel $K^*_q\mathcal{O}_q^*$. In particular, $[E_{q,0} : E_{q,1}] = [E_q^* : K^*_q\mathcal{O}_q^*] = 2$.

3. The homomorphism $\varphi : E_q^* \to E_{q,0}/E_{q,1}^2$, $\alpha \mapsto \alpha\overline{\alpha}^{-1}$ is surjective by Hilbert’s Theorem 90 and has kernel $K^*_qE_{q,0} = K_q^*(E_q^*)^2$. Therefore

$$E_{q,0}/E_{q,1}^2 \cong E_q^*/K^*_qE_{q,0} = E_q^*/K_q^*(E_q^*)^2.$$ 

This isomorphism also gives a method of computing representatives of $E_{q,0}/E_{q,1}^2$ of the form $\lambda/\overline{\lambda}$ with $\lambda \in \mathcal{O}$.

Proof. The first two assertions are obvious. The last one can be seen as follows. The groups $K^*_qE_{q,0}$ and $K^*_q(E_q^*)^2$ are clearly contained in Ker($\varphi$). Conversely, let $\alpha \in$ Ker($\varphi$). Thus $\alpha/\overline{\alpha} = \varepsilon^2$ with $\varepsilon \in E_{q,0}$. Hence $\alpha\varepsilon = \overline{\alpha}\varepsilon \in K^*$ and $\alpha = (\alpha\varepsilon)\varepsilon \in K^*E_{q,0}$. Further, $\varepsilon = \varphi(\lambda)$ for some $\lambda \in E^*$. Hence $\alpha = (\alpha\varepsilon)\lambda/\overline{\lambda} = (\alpha\varepsilon\lambda\overline{\lambda}) \cdot \overline{\lambda}^{-2} \in K^*(E_q^*)^2$. □

The exact value of $E(L_q)$ is known in almost all cases. The following result is due to G. Shimura. However, a simpler proof is given below.

Proposition 5.4.13 Let $\mathfrak{Q}$ be a prime ideal of $\mathcal{O}$ and set $q := \mathfrak{Q} \cap \mathfrak{o}$.

1. If $\mathfrak{Q}$ is unramified or $L_q$ has a Jordan block of odd rank, then $E(L_q) = E_{q,0}$.

2. If $\mathfrak{Q}$ is ramified and $2 \notin q$ then

$$E(L_q) = \begin{cases} E_{q,0} & \text{if } L_q \text{ has a } \mathfrak{Q}^i\text{-modular Jordan block with } i \text{ even,} \\ E_{q,1} & \text{otherwise.} \end{cases}$$

3. If $\mathfrak{Q}$ is ramified and $2 \in q$ then

$$E_{q,0}^2 \subseteq E(L_q) \subseteq E_{q,1}.$$ 

If the rank of some Jordan block of $L_q$ is different from 2, then $E_{q,1} \subseteq E(L_q)$.

Proof. By Algorithm 3.3.2, $L$ splits into $L_1 \perp L_2$ with $\text{rank}(L_1) \leq 2$. If $\text{rank}(L_1) = 1$, then $E(L_q) = E_{q,0}$. If $\text{rank}(L_2) = 2$, then $E_{q,0}^2 \subseteq E(L_q)$. Further, the hyperbolic planes $H(i)$ admit the isometries $\{\text{Diag}(\varepsilon, \varepsilon^{-1}) : \varepsilon \in \mathcal{O}_q^*\}$. In view of Proposition 3.3.5 and Corollary 3.3.20, this only leaves the case that $\mathfrak{Q}$ is ramified, $2 \notin q$ and the scales of all Jordan blocks of $L_q$ have odd valuation. Under these assumptions, Proposition 3.3.5 shows that $(V_q, \Phi)$ is hyperbolic and has a skew-symmetric Gram matrix. But determinants of isometries of such spaces lie in $E_{q,1}$, see for example [Sch85, Theorem 7.6]. □
Theorem 5.4.14 Let \( P \) be the set of all primes ideals \( \mathfrak{q} \) of \( \mathfrak{o} \) (ramified in \( E \)) such that \( \mathcal{E}_{\mathfrak{q},0} \neq \mathcal{E}(L_\mathfrak{q}) \). Set

\[
\mathcal{E}(L) = \prod_{\mathfrak{q} \in P} \mathcal{E}_{\mathfrak{q},0}/\mathcal{E}(L_\mathfrak{q}),
\]

\[
R = \{(\varepsilon \mathcal{E}(L_\mathfrak{q}))_{\mathfrak{q} \in P} \in \mathcal{E}(L) : \varepsilon \in \mathcal{O}^* \text{ such that } \varepsilon \mathfrak{e} = 1\},
\]

\[
H = \{(\varepsilon \mathcal{O}, (\varepsilon \mathcal{E}(L_\mathfrak{q}))_{\mathfrak{q} \in P}) \in J \times \mathcal{E}(L) : \varepsilon \in E \text{ such that } \varepsilon \mathfrak{e} = 1\}.
\]

Consider the map

\[
\Psi : \text{gen}(L) \to J \times \mathcal{E}(L), \quad M \mapsto (\mathcal{E}_L : M \mathcal{O}, (\det(\sigma_q) \mathcal{E}(L_\mathfrak{q}))_{\mathfrak{q} \in P})
\]

where \( \sigma_q \in \text{U}(V_q, \Phi) \) such that \( M_\mathfrak{q} = \sigma_q(L_\mathfrak{q}) \) for all \( \mathfrak{q} \in P \).

1. The map \( \Psi \) induces a bijection between the special genera in \( \text{gen}(L) \) and

\[
(J \times \mathcal{E}(L))/H.
\]

2. Let \( (a_1, \ldots, a_r) \) and \( (\gamma_1, \ldots, \gamma_s) \) be systems of representatives of \( J/J_0 \) and \( \mathcal{E}(L)/R \) respectively. Then \( \{(a_i, \gamma_j)H : 1 \leq i \leq r, 1 \leq j \leq r\} \) is a system of representatives of \( (J \times \mathcal{E}(L))/H \). Thus, the number of special genera in \( \text{gen}(L) \) is

\[
[J : J_0] \cdot [\mathcal{E}(L) : R] = [C : C_0] \cdot [\mathcal{E}(L) : R].
\]

Proof. See [Shi64, Theorems 5.24 and 5.27].

The above theorem immediately gives an algorithm to compute representatives of the isometry classes in a given genus, see [Sch98].

Algorithm 5.4.15 GenusRepresentatives\((L)\)

Input: An \( \mathcal{O} \)-lattice \( L \) in the definite hermitian space \((V, \Phi)\) over \( E \).

Output: A system \( S \) of representatives of the isometry classes in \( \text{gen}(L) \).

1. Let \( \mathcal{B} \) be the set of all prime ideals \( \mathfrak{Q} \) of \( \mathcal{O} \) such that \( L_{\mathfrak{Q} \cap \mathfrak{O}} \) is not modular or \( \mathfrak{Q} \) is a ramified prime ideal over 2.
2. Let \( \mathfrak{P} \notin \mathcal{B} \) be a prime ideal of \( \mathcal{O} \) of minimal norm.
3. Let \( \mathcal{A} = \{\mathfrak{A}_1, \ldots, \mathfrak{A}_r\} \) be a set of ideals of \( \mathcal{O} \), not supported at \( \mathcal{B} \), such that

\[
\{[\mathfrak{A}_i] C_0 : 1 \leq i \leq r\} \cup \{[\mathfrak{P}] C_0\}
\]

generates \( C/C_0 \).
4. Let \( P \) be the set of prime ideals \( \mathfrak{q} \) of \( \mathfrak{o} \) such that \( \mathcal{E}(L_\mathfrak{q}) \) is not (known to be) \( \mathcal{E}_{\mathfrak{q},0} \).
5. Let \( \Lambda \) be a generating set of \( \mathcal{E}(L)/R \) where \( R \) is as in Theorem 5.4.14.
6. for \( \gamma R \in \Lambda \) do
7. For \( \mathfrak{q} \in P \) let \( \beta_\mathfrak{q} \in \mathcal{O} \) with \( \text{ord}_{\mathfrak{q}}(\beta_\mathfrak{q}) \in \{0, 1\} \) such that \( \gamma_\mathfrak{q} \mathcal{E}_{\mathfrak{q},0}^{\mathfrak{q}} = \beta_\mathfrak{q}/\overline{\beta_\mathfrak{q}} \mathcal{E}_{\mathfrak{q},0}^{\mathfrak{q}} \).
8: Compute some $\alpha \in E$ such that $\alpha \beta_q - 1 \in 4q\mathcal{O}_q$ for all $q \in P$ $\alpha \in \mathcal{O}_Q^*$ for all split ideals $Q \in \mathcal{B}$

9: Include $\alpha\mathcal{O}$ to $\mathcal{A}$.

10: end for

11: Initialise the list $S = [S]$ where $S$ is the output of \textsc{IteratedNeighbours}(L, $\mathfrak{P}$).

12: Initialise $i = 1$.

13: while $i \leq \#S$ do

14: for $\mathfrak{A} \in \mathcal{A}$ do

15: Compute a lattice $M \in \text{gen}(L)$ such that $[L' : M]_O = \mathfrak{A}\mathfrak{A}^{-1}$ where $L' \in S[i]$. $\alpha \mathcal{O}$ isometric to $M$ then

16: Append the output of \textsc{IteratedNeighbours}(M, $\mathfrak{P}$) at the end of $S$.

17: end if

18: end for

19: Increment $i$.

20: end while

21: return $\bigcup_{S \in S} S$.

\textbf{Proof.} Suppose the notation of Theorem 5.4.14 and let $L = \bigcup_{S \in S} S$. Corollary 5.2.8 shows that $\bigcup_{L \in \text{cls}(L)}$ is a union of special genera and line 16 ensures that $L$ represents no isometry class twice. In particular, since $h(L)$ is finite, the algorithm terminates. It remains to show that $L$ represents every special genus in $\text{gen}(L)$. For this, let $q \in P$ and write $q\mathcal{O} = \Omega^2$. The element $\alpha$ from line 8 satisfies that $\alpha \beta_q$ is a square in $\mathcal{O}_\Omega^*$. Hence $\alpha \gamma = 1 \in \mathcal{E}(L)$ and therefore $(\mathcal{O}, \gamma)H = (\alpha\mathcal{O}, 1)H$. Theorem 5.4.14 shows that $\{(\mathfrak{A}, 1)H : \mathfrak{A} \in \mathcal{A}\}$ generates $(J \times \mathcal{E}(L))/H$ and that $(J \times \mathcal{E}(L))/H$ acts transitively on the set of special genera in $\text{gen}(L)$ via

$$(J \times \mathcal{E}(L))/H \times \text{gen}(L) \to \text{gen}(L), \quad ((\mathfrak{A}, 1)H, \text{sgen}(L')) \mapsto \text{sgen}(M)$$

where $[L' : M]_O = \mathfrak{A}\mathfrak{A}^{-1}$. Thus the standard orbit enumeration in line 13 eventually reaches every special genus in $\text{gen}(L)$.

\textbf{□}

\textbf{Remark 5.4.16} Here are some hints, how the individual steps of the previous algorithm can be performed in practise.

1. A (non-minimal) generating set $\Lambda$ as in line 5 can be obtained from Remark 5.4.12 if one replaces $\mathcal{E}(L)/R$ by $\prod_{q \in P} \mathcal{E}_{q, 0}/\mathcal{E}_{q, 0}^2$. This does not change the validity of the algorithm.

2. The lattice $M$ from line 15 can be obtained as follows. The choice of $\mathfrak{A}$ implies that $\mathfrak{A} = \mathfrak{P}_1, \ldots, \mathfrak{P}_t, \mathfrak{B}$ with split prime ideals $\mathfrak{P}_i \notin \mathcal{B}$ and some fractional ideal $\mathfrak{B} \in C_0$. Consider the sequence

$L' = L_0, L_1, \ldots, L_t$ where $L_t$ is a $\mathfrak{P}_i$-neighbour of $L_{t-1}$.

Then $M := L_t$ satisfies $[L' : M]_O = \mathfrak{A}\mathfrak{A}^{-1}$.
6 Enumerating genera with small class number

The purpose of this chapter is to present an algorithm which classifies the definite hermitian lattices of rank \( m \) and class number at most \( B \) over any totally real number field. The algorithm proceeds in four steps.

1. Enumerate the possible totally real number fields \( K \), the possible \( K \)-algebras \( E \) and the possible ranks \( m \).
2. Enumerate the possible similarity classes of hermitian spaces of rank \( m \) over \( E \).
3. Enumerate the genera of square-free lattices with class number at most \( B \).
4. Enumerate the similarity classes of all genera with class number at most \( B \).

Throughout this chapter, let \( K \) be a totally real number field of degree \( n \) and let \((V, \Phi)\) be a definite hermitian space over \( E \) of rank \( m \). Further, let \( \mathfrak{o} \) and \( \mathcal{O} \) be maximal orders in \( K \) and \( E \) respectively.

Note that D. Lorch in \([Lor]\) uses a slightly different approach for enumerating the one-class genera of definite quadratic lattices.

6.1 Square-free lattices

This section defines the so-called square-free lattices and shows that every integral lattice can be reduced to a square-free lattice by reduction operators that do not increase class numbers.

**Definition 6.1.1** Let \( \mathcal{L} \) denote the set of all \( \mathcal{O} \)-lattices in \((V, \Phi)\) and let \( L \in \mathcal{L} \). Let \( \mathfrak{P} \) be a maximal two-sided ideal of \( \mathcal{O} \) and set \( p = \mathfrak{P} \cap \mathfrak{o} \). Further, let \( \mathfrak{A} \) be an integral two-sided ideal of \( \mathcal{O} \) such that \( \mathfrak{A} = \mathfrak{A}_p \).

1. If \( E_p \cong K_p \oplus K_p \), then \( L_p \) is said to be *square-free*, if \( L_p \) is unimodular. In all other cases, \( L_p \) is called square-free, if

\[
\mathfrak{P} L_p^\# \subseteq L_p \subseteq L_p^\#.
\]

Moreover, \( L_p \) is called \( \mathfrak{A}_p \)-square-free, if \( L_p \) is square-free and \( \mathfrak{A}_p \subseteq \mathfrak{g}(L_p) \subseteq \mathcal{O}_p \).

2. The lattice \( L \) is said to be *square-free* or \( \mathfrak{A} \)-square-free, if \( L_p \) is square-free or \( \mathfrak{A}_p \)-square-free for all \( p \in \mathfrak{P}(\mathfrak{o}) \).
3. Let $\rho_P$ be the map defined by

$$\rho_P : \mathfrak{L} \to \mathfrak{L}, \quad L \mapsto \begin{cases} 
L + (\mathfrak{P}^{-1}L \cap L^\#) & \text{if } E_p \cong K_p \oplus K_p, \\
L + (\mathfrak{P}^{-1}L \cap \mathfrak{P}L^\#) & \text{otherwise}.
\end{cases}$$

Clearly, if a genus contains some $\mathfrak{A}$-square-free $\mathcal{O}$-lattice, then all lattices in the genus have that property. It is worthwhile to mention that square-free lattices are also called almost or nearly unimodular by some authors.

The maps $\rho_P$ generalize the maps defined by L. Gerstein in [Ger72] to hermitian spaces. They are similar in nature to the $p$-mappings introduced by G. Watson in [Wat62]. Below is a summary of some important properties of these maps $\rho_P$, which will be used later on.

**Remark 6.1.2** Let $L$ be an $\mathcal{O}$-lattice in $(V, \Phi)$. Let $\mathfrak{P}$ be a maximal two-sided ideal of $\mathcal{O}$ and set $p = \mathfrak{P} \cap \mathfrak{a}$.

1. If $q \in \mathfrak{P}(\mathfrak{a}) - \{p\}$, then $(\rho_P(L))_q = L_q$.

2. Suppose $E_p \not\cong K_p \oplus K_p$ and let $L_p = \bigcap_{i \in \mathbb{Z}} L_i$ be a Jordan decomposition where $L_i = (0)$ or $\mathfrak{P}^i\mathcal{O}$-modular. Then

$$\rho_P(L)_p = \bigcap_{i \in \mathbb{Z}} L'_i \quad \text{where} \quad L'_i = \begin{cases} 
L_i & \text{if } i \leq 1, \\
\mathfrak{P}^{-1}L_i & \text{if } i > 1.
\end{cases}$$

3. Suppose $E_p \cong K_p \oplus K_p$ and let $L_p = \bigcap_{i \in \mathbb{Z}} L_i$ be a Jordan decomposition where $L_i = (0)$ or $p^i\mathcal{O}$-modular. Then

$$\rho_P(L)_p = \bigcap_{i \in \mathbb{Z}} L'_i \quad \text{where} \quad L'_i = \begin{cases} 
L_i & \text{if } i < 1, \\
\mathfrak{P}^{-1}L_i & \text{if } i \geq 1.
\end{cases}$$

In particular, $\rho_P(L)$ and $\rho_{\mathfrak{P}}(L)$ are in the same genus.

4. If $L_p$ is integral, then $(\rho_P(L))_p = L_p \iff L_p$ is square-free.

5. If $\mathfrak{Q}$ is a maximal two-sided ideal of $\mathcal{O}$, then $\rho_P \circ \rho_{\mathfrak{Q}} = \rho_{\mathfrak{Q}} \circ \rho_P$.

6. If $L$ is integral, there exist some maximal two-sided ideals $\mathfrak{P}_1, \ldots, \mathfrak{P}_s$ of $\mathcal{O}$ such that

$$L' := (\rho_{\mathfrak{P}_1} \circ \cdots \circ \rho_{\mathfrak{P}_s})(L)$$

is square-free. Moreover, the genus of $L'$ is uniquely determined by $L$.

**Proof.** The first five assertions are obvious and the last follows from the second and third by induction on the largest valuation of the scales of the non-zero Jordan blocks. \qed

**Lemma 6.1.3** Let $L, M$ be $\mathcal{O}$-lattices in $(V, \Phi)$ and let $\mathfrak{P}$ be a maximal two-sided ideal of $\mathcal{O}$.
1. If $L$ and $M$ are (locally) isometric, then so are $\rho_\Psi(L)$ and $\rho_\Psi(M)$. In particular, $\rho_\Psi(\text{gen}(L)) = \text{gen}(\rho_\Psi(L))$.

2. Suppose $\rho_\Psi(M) = L$. Then $\text{Aut}(M)$ is the stabilizer of $M$ under $\text{Aut}(L)$.

3. Suppose $\rho_\Psi(M) = L$ and let $L_1, \ldots, L_h$ represent the isometry classes in $\text{gen}(L)$. The group $\text{Aut}(L_i)$ acts on $\rho_\Psi^{-1}(L_i) \cap \text{gen}(M)$. Let $M_{i,1}, \ldots, M_{i,h_i}$ represent the orbits of this action. Then

\[
\{M_{i,j} : 1 \leq i \leq h, 1 \leq j \leq h_i\}
\]

represents the isometry classes of $\text{gen}(M)$. In particular, $h(M) \geq h(L)$.

4. If $\rho_\Psi(M) = L$, then $\text{Mass}(M) = |\rho_\Psi^{-1}(L) \cap \text{gen}(M)| \cdot \text{Mass}(L) \geq \text{Mass}(L)$.

**Proof.** The lattice $\rho_\Psi(L)$ is constructed from $L$ by taking sums and intersections of (rescaled copies of) $L$ and its dual. All these operations commute with (local) isometries. This shows the first and the second assertions. The third is an immediate consequence of the previous ones: Let $M' \in \text{gen}(M)$. Then $\rho_\Psi(M') \cong L_i$ for some $i$. Without loss of generality $\rho_\Psi(M') = L_i$. Hence $M'$ lies in some orbit under $\text{Aut}(L_i)$, whence $M' \cong M_{i,j}$ for some $j$. So the claimed set represents each isometry class at least once. Suppose $M_{i,j}$ and $M_{r,s}$ are isometric, then so are $L_i$ and $L_r$. This shows $i = r$. But any isometry from $M_{i,j}$ to $M_{i,s}$ induces an isometry on $L_i$. Hence $j = s$. So the claimed set represents each isometry class in $\text{gen}(M)$ uniquely. The last assertion follows from Proposition 4.3.5. Alternatively it can also be deduced from the second and third parts. □

**Definition 6.1.4** Let $G$ be a genus of integral $O$-lattices and let $G'$ be a genus of square-free $O$-lattices. The genus $G$ can be reduced to $G'$, if there exists some maximal twosided ideals $\mathfrak{P}_1, \ldots, \mathfrak{P}_s$ of $O$ and $L \in G$ such that

\[(\rho_{\mathfrak{P}_1} \circ \cdots \circ \rho_{\mathfrak{P}_s})(L) \in G'.\]

Lemma 6.1.3 shows that $G'$ is uniquely determined by $G$.

Lemma 6.1.3 also shows that if $(V, \Phi)$ admits an $O$-lattice with class number $h$, it must admit a square-free $O$-lattice $L$ with class number at most $h$. However, there are infinitely many genera of square-free lattices similar to $\text{gen}(L)$ which necessarily all have the same class number. This is where the $\mathfrak{A}$-square-free lattices come into the game.

**Remark 6.1.5** Let $L$ be a square-free $O$-lattice in $(V, \Phi)$. Let $p_1, \ldots, p_r$ be the prime ideals of $\mathfrak{o}$ that divide $d_{E/K}$ and let $p_iO = \mathfrak{P}_i^2$. Further, let $a$ be an integral ideal of $\mathfrak{o}$ such that $\{b \in \mathcal{I}(\mathfrak{o}) : a \subseteq b \subseteq \mathfrak{o}\}$ represents the classes of the narrow class group $\text{Cl}^\sim(\mathfrak{o})$. Then $\mathfrak{A} = aO \cdot \prod_{i=1}^r \mathfrak{P}_i$ satisfies $\mathfrak{A} = \overline{\mathfrak{A}}$ and there exists some totally positive $a \in K^*$ such that $L^a$ is $\mathfrak{A}$-square-free. Moreover, $a$ is unique up to multiplication with elements from $\mathfrak{o}_{>0}^*$.

**Proof.** The construction of $\mathfrak{A}$ implies that $\mathfrak{A} = \overline{\mathfrak{A}}$. Let $a(L) = cO \cdot \prod_{i=1}^r \mathfrak{P}_i^{e_i}$ with $e_i \in \{0, 1\}$ and some integral ideal $c$ of $\mathfrak{o}$. The choice of $a$ guarantees that there exists a totally positive $a \in K^*$, unique up to multiplication by totally positive units, such that $a^{-1}c \subseteq \mathfrak{o}$ is a divisor of $a$. □
6.2 Partial duals

The maps $\rho_p$ from the previous section act on the (genera of all) $O$-lattices in $(V, \Phi)$ such that class numbers are not increased. This section describes similar maps which actually do preserve class numbers.

**Definition 6.2.1** Let $L$ be an $O$-lattice in $(V, \Phi)$ and let $p \in \mathbb{P}(\mathfrak{o})$ be a prime ideal of $\mathfrak{o}$. The **partial dual** of $L$ at $p$ is the unique $O$-lattice $L^#_p$ in $(V, \Phi)$ that satisfies

$$(L^#_p)_q = \begin{cases} L_q & \text{if } q \neq p, \\ L^#_p & \text{if } q = p \end{cases}$$

for all $q \in \mathbb{P}(\mathfrak{o})$.

**Remark 6.2.2** Let $L, M$ be $O$-lattices in $(V, \Phi)$ and let $p, q \in \mathbb{P}(\mathfrak{o})$.

1. The partial dual $L^#_p$ can be computed explicitly as follows. From the Jordan decomposition of $L_p$ one obtains integers $i$ and $j$ such that $p^i L_p \subseteq L^#_p \subseteq p^j L_p$. Then $L^#_p = (p^i L + L^#) \cap p^j L$.
2. $(L^#_p)^#_q = (L^#_q)^#_p$ and $(L^#_p)^# = L$.
3. If $L$ and $M$ are (locally) isometric, then so are $L^#_p$ and $M^#_p$.
4. $\text{Aut}(L) = \text{Aut}(L^#_p)$ and $h(L) = h(L^#_p)$.

**Proof.** The claimed identity in the first part holds locally at every place of $\mathfrak{o}$. Hence it holds globally. The second assertion follows from the definition of partial duals. The lattice $L^#_p$ is constructed from $L$ by taking sums and intersections of rescaled copies of $L$. These constructions are preserved under isometries. This shows the third part, the inclusion $\text{Aut}(L) \subseteq \text{Aut}(L^#_p)$ as well as $h(L) \geq h(L^#_p)$. The fact that $(L^#_p)^#_p = L$ now finishes the proof of the last assertion. □

**Definition 6.2.3** Two hermitian $O$-lattices $L$ and $M$ are said to be **equivalent**, if there exists some chain of $O$-lattices $L = L_0, L_1, \ldots, L_r = M$ and some prime ideals $p_1, \ldots, p_r$ of $\mathfrak{o}$ such that $L_i$ is similar to the partial dual $L^#_{p_i}$ for all $1 \leq i \leq r$. Note that this induces an equivalence relation on the set of all hermitian $O$-lattices, which preserves automorphism groups.

This equivalence relation induces an equivalence relation on the similarity classes of genera of $O$-lattices, which preserves class numbers.

6.3 Enumerating the possible definite hermitian spaces

The purpose of this section is to enumerate all similarity classes of definite hermitian spaces over number fields that could possibly contain lattices of class number at most $B$ for some fixed integer $B$.

Let $K$ be a totally real number field of degree $n$ and let $(V, \Phi)$ be a definite hermitian space of rank $m$ over $E$. 

94
6.3 Enumerating the possible definite hermitian spaces

6.3.1 The quadratic case

Suppose $E = K$ and $m \geq 3$. The local densities of square-free $\mathfrak{o}$-lattices at a prime ideal $\mathfrak{p}$ over 2 are not known in all cases. For a given $\mathfrak{o}$-lattice $L$, the local factor $\lambda(L_{\mathfrak{p}})$ can be computed explicitly using Proposition 4.3.5, see also Remark 6.3.3 below. But this does not help in enumerating the possible base fields. For that one needs a bound that only depends on $\text{Nr}_{K/Q}(\mathfrak{p})$ and $m$. Such a bound was provided by H. Pfeuffer in his thesis [Pfe71a]:

**Theorem 6.3.1** Let $\mathfrak{p} \in \mathfrak{P}(\mathfrak{o})$ be a prime ideal of norm $q$ over 2 and let $e = \text{ord}_{\mathfrak{p}}(2)$ its ramification index. Further let $L$ be an $\mathfrak{o}$-lattice in $(V, \Phi)$ such that $L_{\mathfrak{p}}$ is square-free. If $m = \text{dim}_K(V) \geq 3$, then

$$\beta(L_{\mathfrak{p}}) \cdot q^{-\text{ord}_{\mathfrak{p}}(\nu(L))(m+1)/2} \leq q^{em} \cdot \begin{cases} 3/2 & \text{if } m = 3 \text{ and } q = 2, \\ 9/8 & \text{if } m = 4 \text{ and } q = 2, \\ 1 & \text{otherwise}. \end{cases}$$

**Proof.** See Korollar 1a, Theorem 2 and Hilfssatz 8 of [Pfe71a]. $\square$

**Corollary 6.3.2** Suppose $(V, \Phi)$ admits an $\mathfrak{o}$-lattice with class number at most 2. If $K = \mathbb{Q}$, then $m \leq 30$. If $K \neq \mathbb{Q}$, then $m \leq 14$ and the root discriminant $d_{K}^{1/n}$ is bounded as follows:

<table>
<thead>
<tr>
<th>$m$</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
<th>13</th>
<th>14</th>
</tr>
</thead>
<tbody>
<tr>
<td>$d_{K}^{1/n}$</td>
<td>24.12</td>
<td>12.06</td>
<td>8.37</td>
<td>6.52</td>
<td>5.33</td>
<td>4.50</td>
<td>3.89</td>
<td>3.42</td>
<td>3.06</td>
<td>2.76</td>
<td>2.52</td>
<td>2.31</td>
</tr>
</tbody>
</table>

If $m \geq 4$, a complete list of the possible fields $K$ is available from [Voi08]. For example, there are only 361 totally real fields $K$ whose root discriminant is below 12.06. The largest one has degree 8.

**Proof.** Let $\gamma_m$ be as in Theorem 4.2.3 and let $L$ be a square-free $\mathfrak{o}$-lattice in $(V, \Phi)$ with class number at most 2. Siegel’s mass formula and Theorem 6.3.1 show that

$$1 \geq \text{Mass}(L) \geq \gamma_{m}^{-n} \cdot d_{K}^{m(m-1)/4} \cdot \text{Nr}_{K/Q}(\nu(L))^{(m+1)/2} \cdot \prod_{\mathfrak{p} \in \mathfrak{P}(\mathfrak{o})} \beta(L_{\mathfrak{p}})^{-1} \cdot \begin{cases} 2^{nm} & \text{if } m \text{ is even}, \\ 2^{n(m+1)/2} & \text{if } m \text{ is odd}. \end{cases}$$

$$\geq \gamma_{m}^{-n} \cdot d_{K}^{m(m-1)/4} \cdot \begin{cases} (8/9)^n & \text{if } m = 4, \\ 1 & \text{if } m \geq 6 \text{ is even}, \\ 2^{-n} \cdot (2/3)^n & \text{if } m = 3, \\ 2^{-n(m-1)/2} & \text{if } m \geq 5 \text{ is odd}. \end{cases}$$
In particular, the root discriminant $d_K^{1/n}$ satisfies

$$d_K^{1/n} \leq \gamma_m^{4/m(m-1)} \cdot \begin{cases} (9/8)^{1/3} & \text{if } m = 4, \\ 1 & \text{if } m \geq 6 \text{ is even}, \\ 3^{2/3} & \text{if } m = 3, \\ 2^{2/m} & \text{if } m \geq 5 \text{ is odd}. \end{cases}$$

The right hand side of the above inequality is less that 1 for $m > 30$ and less than $\sqrt{5}$ for $m \geq 15$. It also yields the claimed bounds on $d_K^{1/n}$. $\square$

The enumeration of all totally real number fields with root discriminants at most 24.12 is out of reach with current methods and computers. Thus, for the ternary quadratic lattices, different methods are needed which will yield better bounds on $d_K^{1/n}$. This case will be discussed in detail in Section 7.3.

**Remark 6.3.3** Let $\mathfrak{p} \in \mathbb{P}(\mathfrak{o})$ be a prime ideal over 2 and let $L$ be an $\mathfrak{o}$-lattice in $(V, \Phi)$. If $\mathfrak{p}$ is unramified, the local factor $\lambda(L_{\mathfrak{p}})$ is given by results of S. Cho, see [Cho15]. In general, one can compute $\lambda(L_{\mathfrak{p}})$ as follows:

1. Compute a chain of minimal $\mathfrak{a}_{\mathfrak{p}}$-overlattices $L_{\mathfrak{p}} = L_0 \subset L_1 \subset \ldots \subset L_r$ where $L_r$ is $\mathfrak{n}(L_{\mathfrak{p}})$-maximal, c.f. Algorithm 3.5.4.

2. Look up $\lambda(L_r)$ from Theorem 4.4.1.

3. Compute $\lambda(L_{\mathfrak{p}})$ by a successive comparison of $\lambda(L_i)$ with $\lambda(L_{i-1})$ for $i = r, \ldots, 1$ using Proposition 4.3.5.

Note that one can speed up this method considerably as follows. As explained in Section 3.4, construct a definite hermitian space $(V', \Phi')$ such that $(V_p, \Phi) \cong (V'_p, \Phi')$. Using Algorithm 3.5.4, construct an $\mathfrak{o}$-lattice $L'_r$ in $(V', \Phi)$ such that $(L'_r)_{\mathfrak{p}}$ is $\mathfrak{n}(L_{\mathfrak{p}})$-maximal. Then $(L'_r)_{\mathfrak{p}} \cong L_r$ and thus $\lambda(L_r) = \lambda((L'_r)_{\mathfrak{p}})$. The maximal $\mathfrak{o}$-sublattices between $L'_r$ and $\mathfrak{p}L'_r$ correspond to the projective lines of the $\mathfrak{o}/\mathfrak{p}$-space $L'_r/\mathfrak{p}L'_r$. The finite group $\text{Aut}(L'_r)$ acts on these sublattices and hence on the projective lines. From orbit representatives and the orbit lengths, one obtains a sublattice $L'_{r-1} \subset L'_r$ such that $(L'_{r-1})_{\mathfrak{p}} \cong L_{r-1}$ as well as the cardinality $\#D((L'_r)_{\mathfrak{p}}, (L'_{r-1})_{\mathfrak{p}})$. Similarly, one can then use the finite group $\text{Aut}(L'_{r-1})$ to speed up the enumeration of $\#U((L'_r)_{\mathfrak{p}}, (L'_{r-1})_{\mathfrak{p}})$. This immediately gives $\lambda((L'_{r-1})_{\mathfrak{p}}) = \lambda(L_{r-1})$. Iterating this procedure finally yields $\lambda(L_{\mathfrak{p}})$.

**Algorithm 6.3.4**

**Input:** An integral ideal $\mathfrak{a}$ of $\mathfrak{o}$ and some integers $m \geq 3$ and $B \geq 1$.

**Output:** A set $\mathcal{L}$ of quadratic spaces over $K$ such that every genus of $\mathfrak{a}$-square-free $\mathfrak{o}$-lattices of rank $m$ and class number at most $B$ is represented by some lattice in exactly one of the spaces in $\mathcal{L}$.

1. Set $M_0 = \gamma_m^{-n} \cdot d_K^{m(m-1)/4}$ where $\gamma_m$ is given by Theorem 4.2.3.
2. Let $P_2 := \{ \mathfrak{p} \in \mathbb{P}(\mathfrak{o}); \mathfrak{p} \mid 2 \}$. 

96
3: Enumerate the finite set \( D := \{ S \subset \mathbb{P}(\mathfrak{o}) \mid M_0 \cdot \prod_{p \in S} \mathcal{L} \leq B/2 \} \) where

\[
\lambda_p' = \begin{cases} 
1 & \text{if } p \mid 2 \\
\frac{m-1}{2} \cdot \frac{\zeta_K}{\zeta_K(1-2j)} & \text{if } p \mid a \text{ and } p \mid 2, \\
\frac{m-2}{2} \cdot \frac{\zeta_K(1-2j)}{\zeta_K(m/2-1)} & \text{if } p \mid a \text{ and } m \text{ is odd}, \\
\frac{m-1}{2} \cdot \frac{\zeta_K}{\zeta_K(p)}(m-1)/2 & \text{if } p \mid 2a \text{ and } m \text{ is even.}
\end{cases}
\]

4: Initialise \( \mathcal{L} = \emptyset \).

5: Let \((u_1, \ldots, u_s)\) be a transversal of \((\mathfrak{o}^*)^2\) in \( \mathfrak{o}^*_{>0} \).

6: for \( S \in D \) and \([b] \in \text{Cl}(\mathfrak{o})\) do

7: Let \( g \) be a totally positive generator of \( b^2 \cdot \prod_{p \in S} p \). If none exists, go to step 6.

8: for \( 1 \leq i \leq s \) do

9: Set \( M_1 := 2^{-n(\frac{m}{2})} \cdot \prod_{j=1}^{m-1} |\zeta_K(1-2j)| \) if \( m \) is odd,

\[
\prod_{j=1}^{m-1} |\zeta_K(1-2j)| \cdot |\zeta_K(m/2-1)| \] if \( m \) is even.

10: Set \( D' := \{ C \subset \mathbb{P}(\mathfrak{o}) \mid \#C \text{ is even and } M_1 \cdot \prod_{p \in S \cup C} \lambda_p'' \leq B/2 \} \) where

\[
\lambda_p'' = \begin{cases} 
\frac{1}{3} \frac{\zeta_K}{\zeta_K(p^{m/2-1})} & \text{if } m \text{ is even, } p \mid 2a \text{ and } p \in S \\
\frac{1}{2} \frac{\zeta_K}{\zeta_K(p^{m/2-1})} & \text{if } m \text{ is even, } p \mid 2a \text{ and } p \notin S, \\
\lambda_p' & \text{otherwise.}
\end{cases}
\]

11: for \( C \in D' \) do

12: Let \((V, \Phi) := \text{QUADRATICFORMFROMINVARIANTS}(m, u, g, C, (0, \ldots, 0))\).

13: Include \((V, \Phi)\) to \( \mathcal{L} \).

14: end for

15: end for

16: end for

17: return \( \mathcal{L} \).

**Proof.** First note that for any rational number \( c \), the set \( \{ p \in \mathbb{P}(\mathfrak{o}) \mid \lambda_p' \leq c \} \) is finite. Thus the set \( D \) is finite. Similarly one sees that \( D' \) is always finite. Hence the algorithm terminates. Let \( L \) be an \( \mathfrak{a} \)-square-free lattice of rank \( m \geq 3 \) and \( b(L) \leq B \). Let \((V, \Phi)\) be its ambient quadratic space and set \( S := \{ p \in \mathbb{P}(\mathfrak{o}) \mid \text{ord}_p(\text{det}(V, \Phi)) \text{ is odd} \} \). It remains to show that \( \mathcal{L} \) contains a unique space isometric to \((V, \Phi)\). If \( m \) is even, let \( F := K(\sqrt{\text{disc}(V, \Phi)}) \). By construction, \( \lambda(L_p) \geq \lambda_p' \) for all \( p \mid 2 \). Lemma 4.2.9 shows that \( \lambda(L_p) \geq 1 \) for all \( p \mid 2 \). Lemma 4.2.9 shows that \( \lambda(L_p) \geq \lambda_p' \) for all \( p \mid 2 \). Again, Lemma 4.2.9 shows that \( q^\text{ord}_p(d_{F/K})(m-1)/2 \cdot \lambda(L_p) \geq \frac{1}{2} q^{(m-1)/2} \) whenever \( m \) is even. Similarly, if \( m \) is odd, then

\[
\lambda(L_p) \geq \frac{1}{2} (q^{m/2} - 1) \left( \frac{(m-1)/2}{m_0/2} \right) q^2 \geq q^{m-1} - \frac{1}{2(q + 1)}
\]
where \( m_0 \) denotes the rank of a unimodular Jordan component of \( L_p \). Hence Siegel’s mass formula shows that

\[
\frac{B}{2} \geq \mathrm{Mass}(L) \geq M_0 \cdot \prod_{p \in S \cup P_2} \lambda'_p
\]

and therefore \( S \in D \). In particular, there exists some fractional ideal \( b \) of \( K \) such that \( \det(V, \Phi) \mathcal{O} = b^2 \cdot \prod_{p \in S} p \) has a totally positive generator and \( b^2 \) is unique up to multiplication by elements in \((K^*)^2\). Whence the class \( \det(V, \Phi)(K^*)^2 \) is eventually represented by some unique product \( u \cdot g \).

Thus \( C \in D' \) and the algorithm therefore constructs a space isometric to \((V, \Phi)\) in line 12 at some point. The fact that the spaces in \( \mathcal{L} \) are pairwise non-isometric follows from the Local-Global Principle.

\[ \square \]

**Remark 6.3.5** Let \( \mathfrak{p} \) be a prime ideal of \( \mathcal{O} \) over 2. Then \( \lambda'_p \) in Algorithm 6.3.4 can be computed from Remark 6.3.3 and the description of all square-free \( \mathcal{O}_p \)-lattices, c.f. Proposition 3.3.11.

### 6.3.2 The hermitian case

Suppose \( E/K \) is a CM-extension of number fields and \( m \geq 2 \). From Lemma 4.2.9 and Theorems 4.5.2 and 4.5.2 it follows that \( \lambda(L_p) \in \frac{1}{2} \mathbb{Z} \) and \( \lambda(L_p) = \frac{1}{2} \) is only possible if \( p \) is ramified in \( E \) and \( m \) is odd. This result combined with Siegel’s mass formula immediately yields the following bounds.

**Proposition 6.3.6** Let \( L \) be an \( \mathcal{O} \)-lattice in \((V, \Phi)\) and let \( \gamma_m \) be as in Theorem 4.2.3.

1. The root discriminant \( d_{K}^{1/n} \) of \( K \) is bounded by

\[
d_{K}^{1/n} < \left( \frac{h(L)^{1/n} \gamma_m}{2\pi} \right)^{2/(m^2-1)}.
\]

2. If \( \mathfrak{p} \in \mathbb{P}(\mathcal{O}) \) is ramified in \( E \), then

\[
h(L) \geq \left( \frac{2\pi}{\gamma_m} \right)^n \cdot d_{K}^{(m^2-1)/2} \cdot \text{Nr}_{K/Q}(\mathfrak{p})^{m(m-(-1)^m)/4-1/2} \cdot \begin{cases} 1 & \text{if } m \text{ is even}, \\ 1/2 & \text{if } m \text{ is odd}. \end{cases}
\]

3. If \( K = \mathbb{Q} \), then \( h(L) > \frac{\pi}{\gamma_m} 3^{m(m-(-1)^m)/4-1/2} \).
Proof. Let \( \chi \) be the non-trivial character of \( \text{Gal}(E/K) \) and let \( Q = [\mathcal{O}^* : \sigma^* \mu(E)] \) be the Hasse unit index of \( E/K \). Siegel’s mass formula 4.2.7 shows that

\[
\frac{h(L)}{\# \mu(E)} \geq \text{Mass}(L) = 2\gamma_m^{-n} \cdot d_K^{m-1/2} \cdot \text{Nr}_{K/Q}(d_{E/K})^{m(-1)^m} \cdot \prod_{i=1}^{m} \lambda_K(\chi^i) \prod_p \lambda(L_p) .
\]

If \( t \geq 1 \), then \( \mathcal{L}_K(\chi_2t, 2t) \cdot \mathcal{L}_K(\chi_2t+1, 2t + 1) = \zeta_K(2t) \frac{\zeta_E(2t+1)}{\zeta_K(2t+1)} > \zeta_E(2t + 1) > 1 \). Thus

\[
\frac{h(L)}{\# \mu(E)} > 2\gamma_m^{-n} \cdot \# \mu(E) \cdot \mathcal{L}_K(\chi, 1) \cdot d_K^{n-1/2} \cdot \text{Nr}_{K/Q}(d_{E/K})^{m(-1)^m} \cdot \prod_p \lambda(L_p) \]

\[
= \left( \frac{2\pi}{\gamma_m} \right)^n \cdot \frac{2 \cdot \# \text{Cl}(E)}{Q \cdot \# \text{Cl}(K)} \cdot \frac{d_K^{(m^2-1)/2}}{d_K^{(m^2-1)/2}} \cdot \text{Nr}_{K/Q}(d_{E/K})^{m(-1)^m/4} \cdot \prod_p \lambda(L_p) \]

\[
\geq \left( \frac{2\pi}{\gamma_m} \right)^n \cdot \frac{d_K^{(m^2-1)/2}}{d_K^{(m^2-1)/2}} \cdot \text{Nr}_{K/Q}(d_{E/K})^{m(-1)^m/4} \cdot \prod_p \lambda(L_p) .
\]

This shows the first two assertions. The last assertion follows from the fact that if \( K = \mathbb{Q} \), then \( d_E \geq 3 \).

\( \Box \)

**Corollary 6.3.7** Suppose that \( m \geq 3 \) and \((V, \Phi)\) admits an \( \mathcal{O} \)-lattice of class number at most 2. If \( K = \mathbb{Q} \), then \( m \leq 16 \). If \( K \neq \mathbb{Q} \), then \( m \leq 12 \) and the root discriminant \( d_{K}^{1/n} \) is bounded as indicated below.

</tbody>
</table>

A complete list of these fields \( K \) is given in [Voi08].

Proof. If \( K = \mathbb{Q} \), the previous result shows that \( \frac{\pi}{\gamma_m} 3^{m(-1)^m/4-1/2} < 2 \) which only holds for \( m \leq 16 \). If \( K \neq \mathbb{Q} \), then loc. cit. implies that

\[
\sqrt{5} \leq d_{K}^{1/n} < \left( \frac{2^{1/2} \gamma_m}{2\pi} \right)^{2(m^2-1)} .
\]

This is only satisfied for \( m \leq 12 \) and the above table lists the values of the right hand side for \( 3 \leq m \leq 12 \).

\( \Box \)

**Remark 6.3.8** Suppose that \( m \geq 3 \) and \((V, \Phi)\) admits an \( \mathcal{O} \)-lattice of class number \( \leq B \). For any fixed field \( K \), Proposition 6.3.6/2 effectively bounds the possible candidates for the relative discriminant \( d_{E/K} \). The set of all quadratic extensions \( E/K \) with given relative discriminant \( d_{E/K} \) can then be obtained from (Magma’s interface to) Class Field Theory.
So for \( m \geq 3 \) and \( B \leq 2 \), one can easily write down all CM-extensions \( E/K \) which might yield a hermitian \( \mathcal{O} \)-lattice of class number at most \( B \). It remains to be discussed, which ambient hermitian spaces \((V, \Phi)\) over \( E \) might occur. This is achieved by the following algorithm.

**Algorithm 6.3.9**

**Input:** Some integral ideal \( \mathfrak{A} \) of \( \mathcal{O} \) such that \( \mathfrak{A} = \overline{\mathfrak{A}} \) and integers \( m \geq 2 \), \( B \geq 1 \).

**Output:** A set \( \mathcal{L} \) of hermitian spaces of dimension \( m \) over \( E \) such that every genus of \( \mathfrak{A} \)-square-free \( \mathcal{O} \)-lattices of rank and class number at most \( B \) is represented by some \( \mathcal{O} \)-lattice in exactly one of the spaces in \( \mathcal{L} \).

1. Let \( M_0 = 2^{1-nm} \cdot \prod_{j=1}^{m} |L_K(\chi^j, 1-j)| \) where \( \chi \) is the non-trivial character of \( \text{Gal}(E/K) \).
2. Enumerate the finite set
   \[
   D = \{ C \subset \mathbb{P}(\mathfrak{o}) ; E_p \not\cong K_p \oplus K_p \text{ for all } p \in C \text{ and } M_0 \cdot \prod_{p \in C} \lambda_p' \leq B/\#(E) \}
   \]
   where \( P = \{ p \in \mathbb{P}(\mathfrak{o}) ; p \mid d_{E/K} \} \) and
   \[
   \lambda_p' = \begin{cases} 
   \frac{1}{2} & \text{if } m \text{ is odd and } p \text{ is ramified in } E, \\
   \frac{1}{2} \text{Nr}_{K/Q}(p)^{m-1} & \text{if } p \text{ is inert in } E \text{ and } p\mathcal{O} \nmid \mathfrak{A}, \\
   1 & \text{otherwise.}
   \end{cases}
   \]
3. Initialiase \( \mathcal{L} = \emptyset \).
4. **for** \( C \in D \) such that \( \#C \) is even **do**
5. As explained in Remark 3.4.2, construct some definite, \( m \)-dimensional hermitian space \((V, \Phi)\) over \( E \) such that
   \[
   \{ p \in \mathbb{P}(\mathfrak{o}) ; \det(V_p, \Phi) \notin N(E_p^*) \} = C .
   \]
6. Include \((V, \Phi)\) to \( \mathcal{L} \).
7. **end for**
8. **return** \( \mathcal{L} \).

**Proof.** First note that for every rational number \( c \), the set
   \[
   \{ p \in \mathbb{P}(\mathfrak{o}) ; E_p \not\cong K_p \oplus K_p \text{ for all } p \in C \text{ and } \lambda_p' \leq c \}
   \]
   is finite. Thus the set \( D \) is finite and so the algorithm terminates. Suppose \( L \) is a \( \mathfrak{A} \)-square-free \( \mathcal{O} \)-lattice of rank \( m \) and class number at most \( B \). Let \((V, \Phi)\) be its ambient hermitian space and set \( C = \{ p \in \mathbb{P}(\mathfrak{o}) ; \det(V_p, \Phi) \notin N(E_p^*) \} \). It remains to show that \((V, \Phi)\) is isometric to some unique space in \( \mathcal{L} \). First, \( \#C \) is even by the product formula for Hilbert symbols. If \( m \) is odd and \( p \) ramifies in \( E \), then \( \lambda(L_p) \geq 1/2 \). In all other cases, \( \lambda(L_p) \geq 1 \). Suppose now \( p \in C \) is not unramified in \( E \). Then \( p \) is inert in \( E \). Let \( q \) be
the norm of \( p \). If \( p \mathcal{O} \) is coprime to \( \mathfrak{a} \), then \( \lambda(L_p) \geq \left| \binom{m}{1} q^{m-1/2} \right| \) by Lemma 4.2.9. So Siegel’s mass formula shows that

\[
B/\#\mu(E) \geq \text{Mass}(L) \geq M_0 \cdot \prod_{p \in \mathcal{O} \cup P} \lambda_p .
\]

Hence \( C \in D \) and thus \((V, \Phi)\) is isometric to a unique space in \( L \) by the Local-Global Principle 2.4.1. \( \square \)

6.3.3 The quaternionic hermitian case

Let \( E \) be a definite quaternion algebra over some totally real number field \( K \). Further, let \((V, \Phi)\) be a definite hermitian space of rank \( m \) over \( E \).

**Proposition 6.3.10** Let \( L \) be an \( \mathcal{O} \)-lattice in \((V, \Phi)\) and let \( \gamma_m \) be as in Theorem 4.2.3. Then

\[
d_K^{1/n} \leq \left( \frac{h(L)/2}{2} \cdot \gamma_m \cdot \prod_{p|d_E/K} \prod_{j=1}^{m} (\text{Nr}_{K/Q}(p)^j + (-1)^j)^{-1/n} \right)^{\frac{2}{m(2m+1)}} .
\]

**Proof.** Without loss of generality, \( L \) is square-free. Proposition 4.2.7 shows that

\[
h(L)/2 \geq \text{Mass}(L) \geq \gamma_m^{-n} d_K^{m(m+1)/2} \prod_{p|d_E/K} \lambda(L_p)
\]

\[
\geq \gamma_m^{-n} d_K^{m(m+1)/2} \prod_{p|d_E/K} \prod_{j=1}^{m} (\text{Nr}_{K/Q}(p)^j + (-1)^j) .
\] \( \square \)

**Corollary 6.3.11** Suppose \((V, \Phi)\) admits an \( \mathcal{O} \)-lattice of class number 1 or 2 and let \( \gamma_m \) be as Theorem 4.2.3. Then \( m \leq 9 \) and the following holds:

1. If \( m = 1 \), then \( d_K^{1/n} \leq 11.60 \). For a complete list of these fields, see [Voi08].
2. If \( m = 2 \), then \( d_K^{1/n} \leq 6.34 \).
3. If \( m = 3 \), then \( K = \mathbb{Q} \) or \( K = \mathbb{Q}(\sqrt{d}) \) where \( d \in \{2, 3, 5, 13, 17\} \).
4. If \( m = 4 \), then \( K = \mathbb{Q} \) or \( K = \mathbb{Q}(\sqrt{d}) \) where \( d \in \{2, 5\} \).
5. If \( m \in \{5, 6\} \), then \( K = \mathbb{Q} \) or \( K = \mathbb{Q}(\sqrt{5}) \).
6. If \( m \in \{7, 8, 9\} \), then \( K = \mathbb{Q} \).
7. The algebra \( E \) satisfies

\[
\prod_{p|d_E/K} \prod_{j=1}^{m} (\text{Nr}_{K/Q}(p)^j + (-1)^j) \leq \gamma_m^n \cdot d_K^{-m(m+1)/2} .
\]
6 Enumerating genera with small class number

Proof. The last assertion is simply equation (6.3.1). If \( K = \mathbb{Q} \), then \( E/K \) is ramified and thus \( 1 \geq \gamma_m^{-1} \prod_{j=1}^{m} (2^j + (-1)^j) \). This inequality only holds for \( m \leq 9 \). Suppose now \( K \neq \mathbb{Q} \). By Proposition 6.3.10, shows that \( \sqrt{5} \leq d_{E/K}^{1/n} \leq \gamma_m^{-1} \prod_{j=1}^{m/2+1} (2^j + (-1)^j) \). This only holds for \( m \leq 6 \). The right hand side is maximal for \( m = 1 \), in which case it yields the upper bound \( d_{E/K}^{1/n} \leq 11.60 \). In particular, \( K \) is contained in the list \([Voi08]\). The result now follows by enumerating all fields \( K \) for which

\[
1 \geq \text{Mass}(L) \geq \gamma_m^{-n} \cdot d_{E/K}^{m(m+1)/2} \left\{ \begin{aligned}
1 & \text{ if } n \text{ is even,} \\
\prod_{j=1}^{m} (q^j + (-1)^j) & \text{ if } n \text{ is odd,}
\end{aligned} \right.
\]

where \( q \) denotes the norm of the smallest prime ideal of ring of integers of \( K \).

\[ \square \]

Remark 6.3.12 Suppose \((V, \Phi)\) contains an \( \mathcal{O}\)-ideal with class number at most 2. Conditions 1.–6. of Corollary 6.3.11 and \([Voi08]\) provide a finite list of candidates for \((K, m)\). For any such pair, the last condition of Corollary 6.3.11 is only satisfied by finitely discriminants \( d_{E/K} \). The corresponding quaternion algebras \( E \) can be constructed explicitly as explained in Remark 3.4.2. Since there is only one isometry class of definite hermitian spaces of rank \( m \) over \( E \), one immediately obtains a finite list of candidates \((V, \Phi)\) that can possibly admit genera of class number one or two.

6.4 Enumerating the square-free genera with bounded class number

The previous section showed how to compute all definite hermitian spaces \((V, \Phi)\) that can possibly admit square-free lattices with a certain class number, provided the rank of the space is sufficiently large. Next is an algorithm to enumerate representatives of the genera of these square-free lattices in \((V, \Phi)\) explicitly.

Algorithm 6.4.1 ALLASQUAREFREELATTICE\((\langle V, \Phi \rangle, B, \mathfrak{A})\)

**Input:** Some definite hermitian space \((V, \Phi)\) over \( E \) of rank \( m \geq 2 \) and \( \text{dim}_{K}(V) \geq 3 \). Some positive integer \( B \) and some integral ideal \( \mathfrak{A} \) of \( \mathcal{O} \) such that \( \mathfrak{A} = \mathfrak{A}/\mathcal{O} \).

**Output:** A set \( \mathcal{S} \) representing the genera of all \( \mathfrak{A}\)-square-free \( \mathcal{O} \)-lattices in \((V, \Phi)\) with class number at most \( B \).

1. if \( E = K \) then
2. \hspace{1cm} Set \( c_0 := \prod_{p\mid m} \text{min}\{\lambda(L) \mid L \text{ a } \mathfrak{A}_p\text{-square-free } \mathcal{O}_p\text{-lattice in } (V_p, \Phi)\} \).
3. \hspace{1cm} if \( m \) is odd then
4. \hspace{2cm} Set \( c := 2^{-m(m-1)/2} \cdot \prod_{i=1}^{m-1/2} |\zeta_K(1-2i)| \cdot c_0 \).
5. \hspace{2cm} Set \( P_0 := \{p \in \mathbb{P}(\mathfrak{O}) \mid p \text{ not } \text{ odd} \} \).
6. else
7. \hspace{1cm} Set \( d := \text{disc}(V, \Phi) \) and \( r := \{p \in \mathbb{P}(\mathfrak{O}) \mid \text{ord}_p(d) \neq 2 \mathbb{Z} \text{ and } p \notdivides 2\} \).
8. \hspace{2cm} Set \( c := 2^{-m(m-2)/2-r} \cdot \prod_{i=1}^{m/2-1} |\zeta_K(1-2i)| \cdot |\mathfrak{S}_K(\chi_d, 1-m/2)| \cdot c_0 \).
9. \hspace{2cm} Set \( P_0 := \{p \in \mathbb{P}(\mathfrak{O}) \mid p \text{ not } \text{ odd} \} \).

102
The previous section showed how to compute the definite hermitian, square-free $O$-lattices of rank $m$ and class number at most $B$. Given these lattices, one can enumerate all genera with bounded class number using Algorithm 6.4.1. Here are some hints how the individual steps of Algorithm 6.4.1 can be performed in practise:

1. The constant $c_0$ in line 2 of the previous algorithm can be computed using Proposition 3.3.11 and Remark 6.3.3.
2. The sets $S_i$ from line 22 can be computed using the results of Section 3.3 and Algorithm LATTICEINGENUS 3.5.6.
3. The check $h(\bigcap_i L_i) \leq B$ in the last line can be done using Kneser’s neighbour method, see Section 5.4. But of course, one should check $\text{Mass}(\bigcap_i L_i) \leq B/w$ first, where $w$ denotes the number of roots of unity of the center of $E$. Note that the needed local factors are given by Lemma 4.2.9 and Section 4.5 or can be computed using Remark 6.3.3.

**Remark 6.4.2** Here are some hints how the individual steps of Algorithm 6.4.1 can be performed in practise:

1. The constant $c_0$ in line 2 of the previous algorithm can be computed using Proposition 3.3.11 and Remark 6.3.3.
2. The sets $S_i$ from line 22 can be computed using the results of Section 3.3 and Algorithm LATTICEINGENUS 3.5.6.
3. The check $h(\bigcap_i L_i) \leq B$ in the last line can be done using Kneser’s neighbour method, see Section 5.4. But of course, one should check $\text{Mass}(\bigcap_i L_i) \leq B/w$ first, where $w$ denotes the number of roots of unity of the center of $E$. Note that the needed local factors are given by Lemma 4.2.9 and Section 4.5 or can be computed using Remark 6.3.3.

**6.5 Enumerating all genera with bounded class number**

The previous section showed how to compute the definite hermitian, square-free $O$-lattices of rank $m$ and class number at most $B$. Given these lattices, one can enumerate all genera with bounded class number using Algorithm 6.4.1. Here are some hints how the individual steps of Algorithm 6.4.1 can be performed in practise:

1. The constant $c_0$ in line 2 of the previous algorithm can be computed using Proposition 3.3.11 and Remark 6.3.3.
2. The sets $S_i$ from line 22 can be computed using the results of Section 3.3 and Algorithm LATTICEINGENUS 3.5.6.
3. The check $h(\bigcap_i L_i) \leq B$ in the last line can be done using Kneser’s neighbour method, see Section 5.4. But of course, one should check $\text{Mass}(\bigcap_i L_i) \leq B/w$ first, where $w$ denotes the number of roots of unity of the center of $E$. Note that the needed local factors are given by Lemma 4.2.9 and Section 4.5 or can be computed using Remark 6.3.3.
similarity classes of genera of definite hermitian \(O\)-lattices of rank \(m\) and class number at most \(B\) by computing preimages under the reduction operators \(\rho_2\) successively. Before this procedure can be stated explicitly, one needs to know how the local factors change under \(\rho_2\) as well as whether this procedure actually terminates. These questions are answered by the following two results.

**Lemma 6.5.1** Let \(L\) and \(M\) be \(O\)-lattices in \((V, \Phi)\) and let \(\mathfrak{P}\) be a maximal twosided ideal of \(O\) such that \(p := \mathfrak{P} \cap o\) is good and unramified in \(E\). Suppose that \(L_p\) is unimodular and \(\rho_2(M) = L\). Then \(\lambda(L_p) = 1\).

If \(F_p \cong K_p \oplus K_p\), then \(\lambda(M_p)\) is given by Lemma 4.2.9. In all other cases, \(M_p = M_0 \perp M_2\) where \(M_i\) is \(\mathfrak{P}^i\)-modular and the local factor \(\lambda(M_p)\) is given by the following table.

<table>
<thead>
<tr>
<th>(\dim_K(E))</th>
<th>(m_0)</th>
<th>(m_2)</th>
<th>(\lambda(M_p))</th>
</tr>
</thead>
<tbody>
<tr>

</table>

Here \(q\) denotes the norm of \(p\), \(m_i = \text{rank}(M_i)\) and \(\varepsilon_i = +1\) if \(\text{disc}(M_i) \in (K^*)^2\) and \(\varepsilon = -1\) otherwise.

**Proof.** This follows immediately from Theorem 4.2.4. \(\square\)

**Theorem 6.5.2** Let \(\mathfrak{P}\) be a maximal twosided ideal of \(O\) and let \(\mathfrak{A}\) be an integral ideal of \(O\) such that \(\mathfrak{A} = \mathfrak{A}\). Let \((L_i)_{i \in \mathbb{N}}\) be a sequence of \(O\)-lattices in \((V, \Phi)\) such that \(\mathfrak{A} \subseteq \mathfrak{A}(L_i) \subseteq O\) and \(L_{i+1} \subseteq \rho_2^{-1}(L_i) - \{L_i\}\) for all \(i\). Then \(\# \{i \in \mathbb{N}; h(L_i) = h(L_{i+1})\}\) is bounded from above by some number which only depends on \(p := \mathfrak{P} \cap o\) and \(L_0\).

**Proof.** The group \(\text{Aut}(L_i)\) is a subgroup of \(\text{Aut}(L_{i-1})\) and \((h(L_i))_{i \in \mathbb{N}}\) is monotonic increasing by Lemma 6.1.3. Loc. cit. also shows that \(h(L_i) = h(L_{i-1})\) implies that \(\rho_2^{-1}(L_{i-1}) \cap \text{gen}(L_i) = \{L_{i-1}\}\) or \(\text{Aut}(L_i) \subseteq \text{Aut}(L_{i-1})\). Note that since \(\text{Aut}(L_i)\) is a subgroup of \(\text{Aut}(L_0)\), the latter case can only happen finitely many times. Hence it suffices to show that there exists some integer \(N \geq 2\), depending only on \(p\), such that \(\rho_2^{-1}(L_{i-1}) \cap \text{gen}(L_i)\) contains some lattice \(X\) different from \(L_i\) for all \(i \geq N\). Let \(\pi \in O\) such that \(\mathfrak{P} = \pi O\) and let \(i \geq 2\). Then \((L_i)_p = M_1 \perp M_2\) where \(M_1\) is square-free and \(\mathfrak{s}(M_2) \subseteq \mathfrak{P}^2\). Note that neither \(M_1\) or \(M_2\) are zero as \((\mathfrak{s}(L_i))_{i \in \mathbb{N}}\) is bounded and \(L_i \neq L_{i+1}\). By Algorithm 3.3.2, \(M_1\) and \(M_2\) have orthogonal decompositions into modular lattices of rank at most 2. For showing the existence of such a lattice \(X\), one may assume that the \(M_i\) itself are modular lattices of rank one or two. Let \(x \in M_1\) and \(z \in M_2\) such that \(Q_\Phi(x,o) = n(M_1)\) and \(Q_\Phi(z,o) = n(M_2)\). If \(M_1\) has rank 2, let \(y \in M_1\) such that \((x,y)\) is a basis of \(M_1\); otherwise set \(y = 0\). Similarly, if \(M_2\) has rank 2, let \(w \in M_2\) such that \((x,w)\) is a basis of \(M_2\); otherwise set \(w = 0\) and set \(X = \Omega(x,y,w)\). Then \(h(X) = h(L_{i-1})\) and \(\mathfrak{s}(X) \subseteq \mathfrak{P}^2\). Hence \(X\) is a modular lattice of rank at most 2 which is different from \(L_i\). Therefore \(X\) is also a modular lattice of rank 1 or 2. Hence \(\text{Aut}(L_i)\) contains a modular lattice of rank 2, and we are done by Lemma 6.1.3. \(\square\)
that \((z, w)\) is a basis of \(M_2\); otherwise set \(w = 0\). Let \(X_1\) and \(X_2\) be the \(\mathcal{O}_p\)-lattices generated by \((x - \pi^{-1}z, y)\) and \((z + \frac{\Phi(z, z)}{\pi Q_\Phi(x, x)}, w + \frac{\Phi(z, w)}{\pi Q_\Phi(x, x)})\) respectively. Let \(X\) be the \(\mathcal{O}\)-lattice which coincides with \(L_i\) at all places of \(\mathfrak{p}\) different from \(p\) and \(X_p = X_1 \perp X_2\). Note that \(s(M_2) \subseteq \mathfrak{P}^!\). So if \(i\) is large enough, then \(X_1 \perp X_2\) is an \(\mathcal{O}_p\)-sublattice of \(L_{i-1}\) different, yet isometric to \(M_1 \perp M_2\) and \(\rho_\mathfrak{P}(X) = \rho_\mathfrak{P}(L_{i-1})\). Explicit bounds for \(i\) depend on whether \(p\) is good or bad and can be worked out case by case. \(\square\)

The computation of all \(\mathcal{O}\)-lattices in \((V, \Phi)\) with a given class number \(B\), can be reduced to the enumeration of square-free lattices as follows.

**Algorithm 6.5.3** \textsc{InverseSearch} \((L, B, \mathfrak{A})\)

**Input:** Some positive integer \(B\), some twosided ideal of \(\mathcal{O}\) such that \(\mathfrak{A} = \mathfrak{A}\) and some \(\mathfrak{A}\)-square-free \(\mathcal{O}\)-lattice \(L\) in \((V, \Phi)\) such that \(h(L) \leq B\).

**Output:** A sequence \(\mathcal{L}\) of \(\mathcal{O}\)-lattices representing the genera \(G\) of all \(\mathcal{O}\)-lattices in \((V, \Phi)\) that satisfy the following conditions:

- \(h(G) \leq B\).
- \(G\) is reducible to \(\text{gen}(L)\).
- \(\mathfrak{A} \subseteq s(M) \subseteq \mathcal{O}\) for all \(M \in G\).

1: Initialise the list \(\mathcal{L} = (L)\) and let \(w\) be the number of roots of unity in the center of \(E\).

2: Let \(P = \{p \in \mathbb{P}(\mathfrak{a}) : \text{p is bad or ramified in } E\) or \(L_p\) is not unimodular or \(\mathfrak{A}_p \neq \mathcal{O}_p\}\).

3: Let \(P = P \cup \{p \in \mathbb{P}(\mathfrak{a}) : \text{Mass}(M) \leq B/w\) for some \(M \in \rho_\mathfrak{P}^{-1}(L)\) where \(\mathfrak{P}\}\) denotes a maximal twosided ideal of \(\mathcal{O}\) over \(p\}.

4: for \(p \in P\) do

5: Set \(i = 1\) and fix some maximal twosided ideal \(\mathfrak{P}\) of \(\mathcal{O}\) over \(p\).

6: while \(i \leq \#\mathcal{L}\) do

7: Let \(\mathcal{M} = \{M \in \rho_\mathfrak{P}^{-1}(\mathcal{L}_i) : M \neq \mathcal{L}_i\) and \(\mathfrak{A} \subseteq s(M)\}\).

8: Let \(S\) be a set of lattices that represent \(\{\text{gen}(M) : M \in \mathcal{M}\) and \(h(M) \leq B\}\).

9: Append the lattices in \(S\) at the end of the list \(\mathcal{L}\).

10: Increment \(i\).

11: end while

12: end for

13: return \(\mathcal{L}\).

**Proof.** The set \(P\) is finite by Lemma 6.5.1. Hence Theorem 6.5.2 shows that the algorithm terminates. Also \(\mathcal{L}\) does not contain two representatives in the same genus. It remains to show that the lattices in \(\mathcal{L}\) represent any given genus \(G\) of integral \(\mathcal{O}\)-lattices in \((V, \Phi)\) that satisfies the three conditions specified at the beginning of the algorithm. By definition, there exist some \(M \in G\) and maximal twosided ideals \(\mathfrak{P}_1, \ldots, \mathfrak{P}_r\) of \(\mathcal{O}\) and some integer \(e_i \geq 1\) such that \((\rho_{\mathfrak{P}_r}^{e_r} \circ \cdots \circ \rho_{\mathfrak{P}_1}^{e_1})(M) = L\). By Lemmata 6.1.3 and 6.5.1 one has \(\mathfrak{P}_i \cap \mathfrak{o} \in P\) for all \(i\). If \(e := \sum e_i\) is zero, then \(M = L\). Suppose now \(e > 0\). The algorithm runs through the list \(P\) in a given order. Since the reduction operators \(\rho_{\mathfrak{P}_i}\) commute, one may suppose that \(\mathfrak{P}_r \cap \mathfrak{o}\) comes after \(\mathfrak{P}_i \cap \mathfrak{o}\) for all \(i < r\). Hence
by induction, the list \( \mathcal{L} \) represents \( \text{gen}(\rho_\mathcal{P}(M)) \). But then, the list \( \mathcal{L} \) also represents \( \text{gen}(M) = G. \)

Again, the check \( h(M) \leq B \) in line 8 of Algorithm 6.5.3 can be done using Kneser’s neighbour method, see Section 5.4. Finally, the way to enumerate all similarity classes of genera of \( \mathcal{O} \)-lattices of rank \( m \) and class number at most \( B \) is paved:

\[ \text{Algorithm 6.5.4 \ ENUMERATE}(K, \mathcal{O}, m, B) \]

**Input:** A totally real number field \( K \) and some maximal order \( \mathcal{O} \) of a \( K \)-algebra \( E \) such that either \( E = K \) or \( E/K \) is a CM-extension or \( E \) is a definite quaternion algebra with center \( K \). Integers \( B \geq 1 \) and \( m \geq 2 \) such that \( m \geq 3 \) whenever \( E = K \).

**Output:** A set \( \mathcal{L} \) representing the similarity classes of all genera of \( \mathcal{O} \)-lattices in hermitian spaces of rank \( m \) over \( E \) having class numbers at most \( B \).

1. Let \( \mathfrak{A} \) be the integral ideal of \( \mathcal{O} \) from Remark 6.1.5.
2. Compute representatives \( (V_1, \Phi_1), \ldots, (V_t, \Phi_t) \) of the isometry classes of all definite hermitian spaces over \( E \) of rank \( m \), that might admit \( \mathfrak{A} \)-square-free \( \mathcal{O} \)-lattices with class numbers at most \( B \), see Algorithms 6.3.4 and 6.3.9 and Remark 6.3.12.
3. For \( 1 \leq i \leq t \) let \( \mathcal{L}_i \) be the output of \( \text{ALLASQUAREFREE}\text{LATTICES}((V_i, \Phi_i), B, \mathfrak{A}). \)
4. Compute the set \( \mathcal{L} = \bigcup_{i=1}^{t} \bigcup_{L \in \mathcal{L}_i} \text{INVERSE}\text{SEARCH}(L, B, \mathfrak{A}). \)
5. Eliminate duplicate entries from \( \mathcal{L} \), i.e. lattices that represent similar genera.
6. **return** \( \mathcal{L} \).

**Proof.** The algorithm terminates since it only makes finitely many calls to algorithms that are already known to terminate. Let \( M \) be an \( \mathcal{O} \)-lattice in some hermitian space \( (V, \Phi) \) of rank \( m \) such that \( h(L) \leq B \). It remains to show that \( \mathcal{L} \) represents a genus similar to \( \text{gen}(M) \). By the choice of \( \mathfrak{A} \), there exists some totally positive element \( a \in K \) such that the rescaled lattice \( M^a \) satisfies \( \mathfrak{A} \subseteq \mathfrak{s}(M^a) \subseteq \mathcal{O} \). Thus \( (V, a\Phi) \) is isometric to \( (V_i, \Phi_i) \) for some \( i \) and one may assume that \( M \subseteq V_i \). Now \( \text{gen}(M) \) reduces to some unique \( \mathfrak{A} \)-square-free genus \( G \). Hence \( G \) is represented by some lattice \( L \) in \( \mathcal{L}_i \) and thus \( \text{gen}(M) \) is represented by some lattice in \( \text{INVERSE}\text{SEARCH}(L, B, \mathfrak{A}) \).

**Remark 6.5.5** In the end, Algorithm 6.5.4 only returns similarity classes of genera. Thus it can be optimized in two ways.

1. The group \( \mathfrak{a}_0^* \) acts on the the isometry classes of all definite hermitian spaces over \( E \) of rank \( m \), that might admit \( \mathfrak{A} \)-square-free \( \mathcal{O} \)-lattices with class numbers at most \( B \) via rescaling. It suffices to let \( (V_1, \Phi), \ldots, (V_t, \Phi_t) \) in step 2 of Algorithm 6.5.4 represent the orbits of that action.

2. One can replace step 3 by the following steps.
6.5 Enumerating all genera with bounded class number

1: Change Algorithm 6.4.1 to only return a set $\mathcal{L}'_i$ representing the $\mathfrak{A}$-square-free $\mathcal{O}$-lattices in $(V_i, \Phi_i)$ of class number at most $B$ such that the rank of the unimodular component of a Jordan composition of $L_p$ has rank at least $m/2$ for all $p \in \mathbb{P}(\mathcal{O})$ such that $\mathfrak{A}_p \neq \mathcal{O}_p$.

2: \textbf{for} $1 \leq i \leq t$ \textbf{do}
3: \quad Let $P = \{ p \in \mathbb{P}(\mathcal{O}) : \mathfrak{A}_p \neq \mathcal{O}_p \text{ and } L_p \text{ is not unimodular for some } L \in \mathcal{L}'_i \}$.
4: \quad \textbf{for} $p \in P$ \textbf{do}
5: \quad \quad \textbf{for} $L \in \mathcal{L}'_i$ such that $L_p$ is not unimodular \textbf{do}
6: \quad \quad \quad Let $a \in K^*$ be totally positive such that $(L^\#)^a$ is $\mathfrak{A}$-square-free.
7: \quad \quad \quad Insert $(L^\#)^a$ into $\mathcal{L}'_i$.
8: \quad \quad \textbf{end for}
9: \quad \textbf{end for}
10: \quad Set $\mathcal{L}_i := \mathcal{L}'_i$.
11: \textbf{end for}

Note that an element $a$ as above always exists, by the choice of $\mathfrak{A}$. Further, $(L^\#)^a$ and $L$ share the same class number. Also note that the set $\mathcal{L}_i$ is usually much smaller than the set $\mathcal{L}_i$ from Algorithm 6.5.4 and thus can be computed much quicker. Now after step 11, the set $\bigcup_i \mathcal{L}_i$ will represent each genus of definite hermitian $\mathfrak{A}$-square-free $\mathcal{O}$-lattices. Hence it is save to replace the sets $\mathcal{L}_i$ in Algorithm 6.4.1 by the ones from above.
Chapter 7: Quadratic lattices with class number at most 2

The purpose of this chapter is to report on the classification of all definite quadratic lattices over totally real number fields of rank at least 3 and class number at most 2.

The classification of all rational quadratic forms with class number 1 is originally due to G. L. Watson who classified these lattices by hand in a long series of papers [Wat63, Wat72, Wat74, Wat78, Wat82, Wat84, Wat]. In [KL13], D. Lorch and the author checked Watson’s computations using the algorithms given in Chapter 6 and found them to be largely correct. They also enumerate all one-class genera in dimensions 4 and 5, for which G. Watson only produced partial results.

In [Kir14], the author classifies the one-class genera of maximal quadratic lattices over totally real number fields having rank at least 3. Very recently, D. Lorch in his thesis successfully extends this classification to all one-class genera over totally real number fields, see [Lor] for details. Prior to that, the literature mostly discussed unimodular lattices over number fields, see [Sch94] and the references therein.

Throughout this chapter, let $E = K$ be a totally real number field of degree $n$ and let $(V, \Phi)$ be a definite quadratic space over $K$ of rank $m$. Further, let $\mathfrak{o}$ be the maximal order in $K$.

### 7.1 The unary case

Suppose $m = 1$ and let $L, L'$ be $\mathfrak{o}$-lattices in $(V, \Phi)$ in the same genus. For any prime ideal $\mathfrak{p}$ of $\mathfrak{o}$, there exists some $x_{\mathfrak{p}} \in K_{\mathfrak{p}}^\times$ such that $L_{\mathfrak{p}} = L_{\mathfrak{p}}'x_{\mathfrak{p}}$ and $x_{\mathfrak{p}}^2 = 1$. Whence $x_{\mathfrak{p}} \in \{\pm 1\}$ and $L_{\mathfrak{p}} = L_{\mathfrak{p}}'$. But then $L' = L$. In particular, any unary $\mathfrak{o}$-lattice has class number one.

### 7.2 The binary case

#### 7.2.1 Definite binary quadratic lattices over totally real number fields

Suppose that $m = 2$. In his seminal book ‘Disquisitiones Arithmeticae’ [Gau01], C. F. Gauß introduces (among many other things) the composition of binary, rational quadratic forms and the notion of (proper) isometry classes and genera. He relates the proper isometry classes in a given genus with the so called ambiguous ideal classes of some quadratic extension of $\mathbb{Q}$. A similar result holds for any totally real number field $K$. The following approach is taken from H. Pfeuffer [Pfe81] and O. Körner [Kör81].
The discriminant \( \text{disc}(V, \Phi) = -\det(V, \Phi) \) is a non-square, as \((V, \Phi)\) is anisotropic. Hence \( F = K(\sqrt{\text{disc}(V, \Phi)}) \) is a quadratic field extension of \( K \). Let \( \sigma \) be the non-trivial Galois automorphism of \( F/K \) and let \( \mathcal{O} \) denote the ring of integers of \( F \). For any subset \( S \) of (a completion of) \( F \), let \( S^1 = \{ x \in S; x\sigma(x) = 1 \} \) be the elements of relative norm 1 in \( S \).

By [Kne02, (6.15)], the even part of the Clifford algebra of \((V, \Phi)\) is isomorphic to \( F \). Further, the space \((V, \Phi)\) is similar to the field \( F \) equipped with the trace bilinear form \( F \times F \rightarrow \mathbb{E}, (x, y) \mapsto \frac{1}{2} T_{F/K}(x\sigma(y)) = \frac{x\sigma(y) + \sigma(x)y}{2} \).

So for the classification of all definite binary quadratic lattices with a given class number, one may assume that \( V = F \) and \( \Phi \) is the bilinear form from above. Then the quadratic form \( Q_\Phi \) associated to \( \Phi \) is the usual relative norm \( \text{Nr}_{F/K}: F \rightarrow K, x \mapsto x\sigma(x) \).

**Lemma 7.2.1** The map \( \Psi: F^1 \rightarrow \text{SO}(F, \Phi), \alpha \mapsto (x \mapsto \alpha x) \) is an isomorphism of groups and \( \sigma \in \mathcal{O}(F, \Phi) \) is an isometry of determinant \(-1\). Similarly, \( F^1_\mathfrak{p} \cong \text{SO}(F_\mathfrak{p}, \Phi) \) for all \( \mathfrak{p} \in \mathbb{P}(\mathfrak{o}) \).

**Proof.** Only the surjectivity of \( \Psi \) requires proof. Let \( \varphi \in \text{SO}(F, \Phi) \). Then \( \alpha := \varphi(1) \in F^1 \). Let \( x \in F^* \) be such that \( T_{F/K}(x) = 0 \). Then \((1, x)\) is an orthogonal basis of \((F, \Phi)\). Hence its image under \( \varphi \) must also be such a basis. Thus \( \varphi(x) = \alpha sx \) for some \( s \in K^* \). Comparing norms shows that \( s^2 = 1 \). Together with \( \det(\varphi) = +1 \) this implies that \( s = 1 \) and therefore \( \varphi = \Psi(\alpha) \). \( \square \)

Given any \( \mathfrak{o} \)-lattice \( L \) in \((F, \Phi)\), let \( h^+(L) \) denote the proper class number of \( L \), i.e. the number of proper isometry classes in the genus of \( L \). Let \( \Lambda = \mathcal{O}_r(L) \) be the (right) order of \( L \). The previous lemma shows that \( \text{Aut}^+(L) = \Lambda^1 \) is finite. Thus \( \Lambda^1 = \mu(F) \cap \Lambda \) is the group of roots of unity in \( \Lambda^* \). Moreover, \( \sigma \in \text{Aut}(\Lambda) − \text{Aut}^+(\Lambda) \) shows that \( \text{cls}(\Lambda) = \text{cls}^+(\Lambda) \). Hence

\[
h(\Lambda) \leq h^+(\Lambda) \leq 2h(\Lambda) - 1. \tag{7.2.1}\]

In particular, \( h(\Lambda) = 1 \iff h^+(\Lambda) = 1 \).

**Lemma 7.2.2** Let \( L \) be an \( \mathfrak{o} \)-lattice in \((F, \Phi)\) and let \( \Lambda = \mathcal{O}_r(L) \).

1. \( L \) is an invertible, fractional ideal of \( \Lambda \).
2. The set \( \text{gen}(\Lambda) \) forms a group with respect to the usual multiplication of ideals and \( \text{cls}^+(\Lambda) \) is a subgroup.
3. The map \( \Psi: \text{gen}(\Lambda) \rightarrow \text{gen}(L), M \mapsto LM \) is a bijection, which preserves proper isometry classes.
4. \( h^+(L) = h^+(\Lambda) = [\text{gen}(\Lambda) : \text{cls}^+(\Lambda)] \).
7.2 The binary case

Proof. The product $L\sigma(L)$ is generated as $\Lambda$-module by $\{x\sigma(x) : x \in L\}$. But then $L\sigma(L) = \text{Nr}_{F/K}(L) \cdot \Lambda$. Thus $\text{Nr}_{F/K}(L)^{-1} \sigma(L)$ is the inverse of $L$. An $\mathfrak{p}$-lattice $X$ is in $\text{gen}(\Lambda)$ if and only if for all $\mathfrak{p} \in \mathfrak{F}(\mathfrak{o})$ such that $X_\mathfrak{p} \neq \Lambda_\mathfrak{p}$, there exists some $x_\mathfrak{p} \in F^1_\mathfrak{p}$ with $X_\mathfrak{p} = \Lambda_\mathfrak{p}x_\mathfrak{p}$. The second part follows immediately from this characterization. Similarly, one characterizes the elements in $\text{gen}(L)$. This shows that $\Psi$ is well-defined. It is a bijection, since $L$ is invertible. Two lattices $L_1, L_2 \in \text{gen}(L)$ are properly isometric if and only if $L_1 = L_2c$ for some $c \in F^1$. This is equivalent to $L^{-1}L_1 = L^{-1}L_2c$, i.e. $\Psi^{-1}(L_1) = \Psi^{-1}(L_2)c$. Hence $L_1 \in \text{cls}^+(L_2) \iff \Psi^{-1}(L_1) \equiv \Psi^{-1}(L_2) \pmod{\text{cls}^+(\Lambda)}$. So $\Psi^{-1}$ and thus $\Psi$ preserve proper isometry classes and the number of such classes is equal to the index $[\text{gen}(\Lambda) : \text{cls}^+(\Lambda)]$.

The previous lemma shows that the classification of all $\mathfrak{o}$-lattices in $(F, \Phi)$ with a certain proper class number boils down to classification of all $\mathfrak{o}$-orders $\Lambda$ in $F$ with that proper class number. The latter number can be related to $h^+(f)$ as follows.

Theorem 7.2.3 Let $\Lambda$ be an $\mathfrak{o}$-order in $F$ with conductor $\mathfrak{c}$. Then $h^+(\Lambda) \geq h^+(f)$ and

$$h^+(\Lambda) \cdot [f^1 : \Lambda^1] = h^+(f) \cdot \prod_{\mathfrak{p}|\mathfrak{c}} [f^1_\mathfrak{p} : \Lambda^1_\mathfrak{p}].$$

Proof. The proof follows [Kör81, Lemma 3]. The case $\mathfrak{c} = \mathfrak{o}$ is trivial, so suppose $\mathfrak{c} \neq \mathfrak{o}$. The map $\varphi : \text{gen}(\Lambda) \to \text{gen}(f)$, $L \mapsto Lf$ is a group homomorphism. Let $M \in \text{gen}(f)$. For every prime ideal $\mathfrak{p}$ of $\mathfrak{o}$, there exists some $x_\mathfrak{p} \in F^1_\mathfrak{p}$ such that $M_\mathfrak{p} = f^1_\mathfrak{p}x_\mathfrak{p}$ and one can choose $x_\mathfrak{p} = 1$ at all but finitely many places. Hence there exists some $\mathfrak{o}$-lattice $L$ such that $L_\mathfrak{p} = \Lambda_\mathfrak{p}x_\mathfrak{p}$ everywhere. This shows that $\varphi$ is onto with kernel $\text{Ker}(\varphi) = \left\{ \bigcap_{\mathfrak{p}|\mathfrak{c}} (F \cap \Lambda_\mathfrak{p}x_\mathfrak{p}) : x_\mathfrak{p} \in f^1_\mathfrak{p} \right\}$.

This yields the first assertion and an epimorphism $\psi : \text{gen}(\Lambda) / \text{cls}^+(\Lambda) \to \text{gen}(f) / \text{cls}^+(f)$ such that $\text{Ker}(\psi) \cong \text{Ker}(\varphi) / (\text{Ker}(\varphi) \cap \text{cls}^+(\Lambda))$.

Further,

$$\prod_{\mathfrak{p}|\mathfrak{c}} f^1_\mathfrak{p} \to \text{Ker}(\varphi), \ (x_\mathfrak{p}) \mapsto \bigcap_{\mathfrak{p}|\mathfrak{c}} (F \cap \Lambda_\mathfrak{p}x_\mathfrak{p})$$

is a group epimorphism with kernel $\prod_{\mathfrak{p}|\mathfrak{c}} \Lambda^1_\mathfrak{p}$ and therefore $\text{Ker}(\varphi) \cong \prod_{\mathfrak{p}|\mathfrak{c}} f^1_\mathfrak{p} / \Lambda^1_\mathfrak{p}$.

Finally, note that $\text{Ker}(\varphi) \cap \text{cls}^+(\Lambda) = \{x\Lambda : x \in f^1\} \cong f^1 / \Lambda^1$. Combining the above indices shows that $h^+(\Lambda) = h^+(f) \cdot \# \text{Ker}(\psi) = h^+(f) \cdot [f^1 : \Lambda^1]^{-1} \cdot \prod_{\mathfrak{p}|\mathfrak{c}} [f^1_\mathfrak{p} : \Lambda^1_\mathfrak{p}]$. $\square$
In particular, there are only finitely many conductors $\mathfrak{c}$ such that $h^+(\Lambda) \leq B$ for any given bound $B$. It is worth mentioning that, O. Körner expresses $[f^1 : \Lambda^1]^{-1} \cdot \prod_p [f^1_p : \Lambda^1_p]$ in terms of some invariants of $\text{gen}(L)$ making the above theorem even more explicit, see [Kör81, Theorem 2] for details.

What remains is a study of the proper class number of $f$, which is classical. Let $\mathcal{I}(f)$ be the group of fractional $f$-ideals and consider the following subgroups.

- $\mathcal{P} := \{ x f ; x \in F^* \}$ and $ \mathcal{P}_0 := \{ x f ; x \in K^* \}$.
- $\mathcal{A} := \{ a \in \mathcal{I}(f) ; a = \sigma(a) \}$ the subgroup of ambiguous ideals.
- $\mathcal{I}_0 := \{ a f ; a \in \mathcal{I}(\mathfrak{o}) \}$ the image of $\mathcal{I}(\mathfrak{o})$ in $\mathcal{I}(f)$.

Hilbert’s Theorem 90 shows that the group homomorphism

$$\mathcal{I}(f) \to \text{gen}(f), \ a \mapsto a \sigma(a)^{-1}$$

is actually onto. Hence it induces an group epimorphism $\mathcal{I}(f) \to \text{gen}(f) / \text{cls}^+(f)$. The kernel of this epimorphism is $\mathcal{A} \mathcal{P}$ and thus

$$\text{gen}(f) / \text{cls}^+(f) \cong \mathcal{I}(f) / \mathcal{A} \mathcal{P}.$$ 

To evaluate the index $h^+(f) = [\mathcal{I}(f) : \mathcal{A} \mathcal{P}]$, consider the diagram

\[
\begin{array}{c}
\mathcal{I}(f) \\
\downarrow \\
\mathcal{A} \mathcal{P} \\
\downarrow \\
\mathcal{P} \\
\uparrow \\
\mathcal{A} \cap \mathcal{P} \\
\downarrow \\
\mathcal{P}_0 \\
\mathcal{I}_0 \\
\# \text{Cl}(K)
\end{array}
\]

were $r$ denotes the number of prime ideals of $\mathfrak{o}$ that ramify in $F$.

By Hilbert’s Theorem 90, $\varphi : F^* \to F^1$, $x \mapsto x \sigma(x)^{-1}$ is an epimorphism of groups with kernel $K^*$. For $x \in F^*$, the ideal $xf$ is ambiguous if and only if $\varphi(x) \in f^1$. Let $U = \{ x \in F^* ; \varphi(x) \in f^1 \}$. Then $U \to (\mathcal{A} \cap \mathcal{P})/\mathcal{P}_0$, $x \mapsto xf$ is a group epimorphism with kernel $K^*f^1$. Hence

$$\mathcal{A} \cap \mathcal{P} / \mathcal{P}_0 \cong U / K^*f^1.$$
Further, $\varphi$ induces isomorphisms $U/K^*f^* \cong f^1/\varphi(f^*)$ and $f^*/o^*f^1 \cong \varphi(f^*)/(f^1)^2$. From $[f^1 : (f^1)^2] = 2$, it follows that

$$[A \cap \mathcal{P} : \mathcal{P}_0] = 2/Q$$

where $Q = [f^* : \mu(F)o^*] \in \{1, 2\}$ denotes the Hasse unit index of $F/K$. Comparing indices yields the following theorem.

**Theorem 7.2.4** Let $r$ be the number of prime ideals of $\mathfrak{o}$ that ramify in $F$ and let $Q = [f^* : \mu(F)o^*]$ be the Hasse unit index of $F/K$. Then

$$h^+(f) = [I(f) : \mathcal{AP}] = \frac{\# \text{Cl}(F)}{\# \text{Cl}(K)} \cdot \frac{1}{Q \cdot 2^{r-1}}.$$ 

In particular, any CM-extension $F/K$ with relative class number $\frac{\# \text{Cl}(F)}{\# \text{Cl}(K)}$ equal to 1 yields definite, binary quadratic $\mathfrak{o}$-lattices with class number one. However, the exact list of all CM-fields with relative class number one is currently unknown. See [LK06] for an overview of the problem. Thus the classification of all definite, binary quadratic forms with class number one is out of reach with current methods.

Provided that there are infinitely many real quadratic fields of class number one, [Kör81, Theorem 1] shows that there are infinitely many indefinite, binary quadratic lattices with class number one over the integers.

Despite the fact that Theorem 7.2.4 is ineffective, the enumeration of all definite binary quadratic lattices is still a finite problem. The result is due to A. Earnest and D. Estes [EE81].

**Theorem 7.2.5** Given any positive integer $B$, there are only finitely many similarity classes of definite binary quadratic forms over totally real number fields with class number at most $B$.

**Proof.** See [EE81, Section 5].

### 7.2.2 Definite binary quadratic lattices over the rationals

While Theorem 7.2.4 does not allow a classification of all binary quadratic forms of class number one in general, it does so for $K = \mathbb{Q}$ under the assumption of the Generalized Riemann Hypothesis (GRH). The discriminants of the maximal orders corresponding to these forms are L. Euler’s well known 65 idoneal numbers. The classification is based on the following observation and Louboutin’s bound which will be recalled in Theorem 7.2.7.

**Remark 7.2.6** Let $\Lambda$ be an imaginary quadratic $\mathbb{Z}$-order. Then

1. $h(\Lambda) = 1 \iff h^+(\Lambda) = 1$.
2. $h(\Lambda) = 2 \iff h^+(\Lambda) \in \{2, 3\}$. 

113
Proof. By equation 7.2.1, only the implication \( h^+(\Lambda) = 3 \implies h(\Lambda) = 2 \) requires proof. Let \( I \) be a fractional ideal of \( \Lambda \) such that \( \text{cls}^+(I) \) generates \( \text{gen}(\Lambda)/\text{cls}^+(\Lambda) \cong C_3 \). Suppose \( h(\Lambda) \neq 2 \). Then \( h(\Lambda) = 3 \) and thus \( \text{cls}(L) = \text{cls}^+(L) \) for all \( L \in \text{gen}(\Lambda) \). In particular, \( \sigma(I) \in \text{cls}^+(I) \). By Hilbert’s Theorem 90, one may assume that \( \sigma(I) = 1 \) is ambiguous. Since \( \mathbb{Q} \) has class number one, this implies that \( aI \) is a product of ramified ideals of \( \Lambda \) for some \( a \in \mathbb{Q}^* \). But then \( \text{cls}^+(I) \) has order at most 2 which yields the desired contradiction. \( \Box \)

**Theorem 7.2.7 ([Lou90, Theorem 1])** Let \( F \) be an imaginary quadratic number field. Assuming (GRH), one has

\[
\# \text{Cl}(F) \geq \frac{\pi \sqrt{d_F}}{3 \exp(1) \ln d_F}.
\]

Suppose now \( F \) is an imaginary quadratic number field with maximal order \( \mathfrak{f} \) such that \( h^+(\mathfrak{f}) \leq B \). If (GRH) holds, then Theorems 7.2.4 and 7.2.7 imply that

\[
\frac{\sqrt{d_F}}{\ln d_F} \leq \frac{3 \exp(1)}{\pi} 2^{r-1} B < 2.6 \cdot 2^{r-1} B \tag{7.2.2}
\]

where \( r \) denotes the number of primes that ramify in \( F \). Thus \( d_F \) is a product of \( r \) coprime integers from \( \{4, 8\} \cup \{p \in \mathbb{Z} ; p \text{ an odd prime} \} \). In particular, the left hand side of equation 7.2.2 tends to \( \infty \) as \( r \to \infty \). For example in the case \( B = 3 \), one checks that \( r \leq 9 \) and \( 9973 \) is the largest possible prime divisor of \( d_F \). An explicit search using *Magma* yields the following result. The first part is due to P. Weinberger [Wei73].

**Theorem 7.2.8** Assuming (GRH), the following holds.

1. There are 65 maximal, imaginary quadratic \( \mathbb{Z} \)-orders \( \mathfrak{f} \) such that \( h^+(\mathfrak{f}) = 1 \). The discriminants of these orders are Euler’s idoneal numbers. They are listed in Table 7.1.

2. There are 161 maximal, imaginary quadratic \( \mathbb{Z} \)-orders \( \mathfrak{f} \) such that \( h^+(\mathfrak{f}) = 2 \).

3. There are 338 maximal, imaginary quadratic \( \mathbb{Z} \)-orders \( \mathfrak{f} \) such that \( h^+(\mathfrak{f}) = 3 \).

A list of these orders is available from [Kir16].

Suppose now \( \Lambda \) is a \( \mathbb{Z} \)-suborder of \( \mathfrak{f} \) with conductor \( c \neq 1 \) such that \( h^+(\Lambda) \leq B \). Theorem 7.2.3 shows that \( h^+(\mathfrak{f}) \leq h^+(\Lambda) \leq B \). Hence for all orders \( \mathfrak{f} \) from Theorem 7.2.8, one simply has to compute the possible conductors that yield orders with proper ideal class number at most \( B \). If \( p \mid c \) and \( p \nmid 2 d_F \), then \( \mathfrak{f}_p^1 \) is mapped to the elements of \( \mathfrak{f}_p/\mathfrak{f}_p^1 \) of norm one and \( \Lambda^1_p \) is mapped to \( \{ \pm 1 \} \). Hence \( [\mathfrak{f}_p^1 : \Lambda^1_p] \geq \frac{B-1}{2} \). Thus \( c \) is supported at

\[ \{ p ; p \mid 2 d_F \text{ or } p \leq 1 + 2B[\mathfrak{f}^1 : \{ \pm 1 \}]/h^+(\mathfrak{f}) \} \].
7.3 The ternary case

This yields all possible prime divisors of \( c \). The same argument as used in Theorem 7.2.3 actually shows that \( h^+(\Lambda') \geq h^+(\Lambda) \) for any suborder \( \Lambda' \) of \( \Lambda \). Thus for any prospective prime divisor \( p \) of \( c \) one can test the \( \sigma \)-suborders of \( \mathfrak{f} \) having conductor \( p, p^2, p^3, \ldots \) until one reaches an order \( \Lambda \) with \( h^+(\Lambda) > B \). This gives an upper bound for the \( p \)-adic valuation of \( c \) and thus all possible conductors \( c \). If one applies this strategy to all orders given by Theorem 7.2.8, one obtains the result below.

**Theorem 7.2.9** Assuming (GRH), the following holds.

1. There are 101 imaginary quadratic \( \mathbb{Z} \)-orders \( \Lambda \) such that \( h^+(\Lambda) = 1 \). They are listed in Table 7.1.
2. There are 324 imaginary quadratic \( \mathbb{Z} \)-orders \( \Lambda \) such that \( h^+(\Lambda) = 2 \).
3. There are 683 imaginary quadratic \( \mathbb{Z} \)-orders \( \Lambda \) such that \( h^+(\Lambda) = 3 \).

A list of these orders is available from [Kir16].

The above result and Remark 7.2.6 immediately yield a classification of all definite binary quadratic lattices of class number at most 2 over the rationals.

**Corollary 7.2.10** Assuming (GRH), there are 101 imaginary quadratic \( \mathbb{Z} \)-orders \( \Lambda \) such that \( h(\Lambda) = 1 \) and 1007 imaginary quadratic \( \mathbb{Z} \)-orders \( \Lambda \) such that \( h(\Lambda) = 2 \).

7.3 The ternary case

Suppose \( m = 3 \). The bound given in Corollary 6.3.2 is simply not good enough to be able to write down all possible base fields \( K \) that might admit one-class genera of definite,
ternary quadratic forms. However, there is a well known correspondence between ternary quadratic forms and quaternion orders due to J. Brzeziński [Brz80, Brz82] and M. Peters [Pet69]. It is based on work of M. Eichler [Eic52] and H. Brandt [Bra43]. In [KL16], D. Lorch and the author used this correspondence to classify all ternary quadratic forms of class number at most 2. The section at hand gives a summary of the method used.

By [Kne02, Section 6], the even part of the Clifford algebra of \((V, \Phi)\) is a definite quaternion algebra \(Q\). Let \(\sigma : Q \to Q\) be its canonical involution and let \(\text{nr}_{Q/K}\) and \(\text{tr}_{Q/K}\) denote the reduced norm and trace of \(Q\). By [Kne02, (6.20)], the trace zero subspace \(Q^0 := \{x \in Q; \text{tr}_{Q/K}(x) = 0\}\) equipped with the trace bilinear form

\[ Q^0 \times Q^0 \to K, \quad (x, y) \mapsto \frac{1}{2} \text{tr}(x\sigma(y)) \]

is similar to \((V, \Phi)\). So for the classification of all definite ternary quadratic lattices with a given class number, one may assume that \(V = Q^0\) and \(\Phi\) is the bilinear form from above. Its associated quadratic form \(Q_{\Phi}\) is then the reduced norm \(\text{nr}_{Q/K}\).

An \(\mathcal{O}\)-order \(O\) in \(Q\) is called Gorenstein, if the inverse reduced different

\[ O^\# := \{x \in Q; \text{tr}_{Q/K}(xO) \subseteq \mathcal{O}\} \]

is an invertible twosided ideal of \(O\). For example maximal or more generally hereditary orders are Gorenstein. For any order \(O\), the ideal \(D(O) := \text{nr}_{Q/K}(O^\#)^{-1}\) of \(\mathcal{O}\) is called the reduced discriminant of \(O\). If \(O\) is a maximal order in \(Q\), then \(D(O) = d_{Q/K}^{1/2}\) is the product of all prime ideals of \(\mathcal{O}\) that ramify in \(Q\). Two \(\mathcal{O}\)-orders \(O, O'\) in \(Q\) are said to be of the same type, if \(O_p\) and \(O'_p\) are isomorphic (i.e. conjugate) for all \(p \in \mathbb{P}(\mathcal{O})\). The set of all orders in \(Q\) which are of the same type as \(O\) is a union of finitely many isomorphism classes. The number of the classes is called the type number of \(O\). Note that any order is contained in some canonical Gorenstein order, the so-called Gorenstein closure. Further the type number of an order always agrees with the type number of it Gorenstein closure, see Section 2 of [KL16] for details. Hence the classification of all orders with given type number boils down to the enumeration of all Gorenstein orders with that type number.

If \(L\) is an \(\mathcal{O}\)-lattice in \((Q^0, \Phi)\), then

\[ \mathcal{O}(L) := \mathcal{O} + \sum_{x, y \in L} n(L)^{-1} \cdot xy \]

is a Gorenstein order in \(Q\) (see [Pet69, Satz 7] and [Brz82, Proposition 2.3]). Conversely, if \(O\) is a Gorenstein order in \(Q\) then

\[ \mathcal{L}(O) := D(O) \cdot (O^\# \cap Q^0) \]

is an \(\mathcal{O}\)-lattice in \((Q^0, \Phi)\).

**Theorem 7.3.1** Let \(Q\) be a quaternion algebra over some number field \(K\) and let \(L, L'\) be \(\mathcal{O}\)-lattices in \((Q^0, \Phi)\).
7.3 The ternary case

1. Each Gorenstein order $\mathcal{O}$ in $\mathbb{Q}$ satisfies $\mathcal{O} = \mathcal{O}(\mathcal{L}(\mathcal{O}))$.

2. There exists a fractional ideal $\mathfrak{a}$ of $\mathfrak{o}$ such that $\mathfrak{a}L = \mathcal{L}(\mathcal{O}(L))$.

3. $\mathcal{O}(L)$ and $\mathcal{O}(L')$ are isomorphic if and only if $L'$ is isometric to $\mathfrak{a}L$ for some fractional ideal $\mathfrak{a}$ of $\mathfrak{o}$.

Proof. The first assertion follows from [Brz82, Proposition 3.2] and it implies $\mathcal{O}(L) = \mathcal{O}(\mathcal{L}(\mathcal{O}(L)))$. Hence $L$ and $\mathcal{L}(\mathcal{O}(L))$ differ by some fractional ideal as [Eic52, Satz 14.1] shows. The last part is proven in [Brz80, Corollary 3.10].

The two constructions $\mathcal{O}$ and $\mathcal{L}$ are compatible with taking completions. This shows the following result.

**Corollary 7.3.2** Let $L$ be a ternary $\mathfrak{o}$-lattice in $(\mathbb{Q}, \Phi)$. Then the class number of $\text{gen}(L)$ coincides with the type number of $\mathcal{O}(L)$.

Recently J. Voight came up with a functorial correspondence between ternary quadratic forms and quaternion orders which preserves class numbers [Voi11]. Using either correspondence shows that the classification of all definite ternary quadratic forms over $K$ with class number $h$ is equivalent to the enumeration of all definite quaternion Gorenstein orders over $K$ with type number $h$.

Let $\mathcal{O}$ be a Gorenstein order in $\mathbb{Q}$ and let $p \in \mathbb{P}(\mathfrak{o})$. There exists some twosided ideal $I$ of $\mathcal{O}$ such that $I/p\mathcal{O}$ is the radical of the $\mathfrak{o}/p$-algebra $\mathcal{O}/p\mathcal{O}$. The radical idealizer process $\text{Id}_p(\mathcal{O})$ of $\mathcal{O}$ is the Gorenstein closure of the right order of $I$. The radical idealizer process is similar to the reduction operators $\rho_p$ from Definition 6.1.1, as it satisfies the following conditions.

- $(\text{Id}_p(\mathcal{O}))_p = \mathcal{O}_p$ if and only if $\mathcal{O}_p$ is hereditary, c.f. [Rei03, Chapter 39].
- $\text{Id}_q(\text{Id}_p(\mathcal{O})) = \text{Id}_p(\text{Id}_q(\mathcal{O}))$ for all $q \in \mathbb{P}(\mathfrak{o})$.
- The type number of $\mathcal{O}$ is at least the type number of $\text{Id}_p(\mathcal{O})$, c.f. [KL16, Lemma 5.4].

In particular, if $K$ admits a definite, ternary quadratic $\mathfrak{o}$-lattice with class number $h$, it also admits a definite, hereditary, quaternion order with type number at most $h$.

**Theorem 7.3.3 (Eichler’s Mass formula)** Let $\mathcal{O}$ be a hereditary order in $\mathbb{Q}$. Write $\mathcal{D}(\mathcal{O}) = d_{Q/K}^{1/2}l$ for some integral ideal $l$ of $\mathfrak{o}$. Further let $\mathcal{O}_1, \ldots, \mathcal{O}_t$ represent the isomorphism classes of all orders in $\mathbb{Q}$ that are of the same type as $\mathcal{O}$. Then

$$\mathcal{M} (\mathcal{O}) := \sum_{i=1}^t \frac{h(\mathcal{O}_i)}{[\mathcal{O}_i^* : \mathfrak{o}^*]} = 2^{1-n} \cdot |\zeta_K(-1)| \cdot \# \text{Cl}(K) \cdot \prod_{p|d_{Q/K}^{1/2}} (N_{K/Q}(p) - 1) \cdot \prod_{p|l} (N_{K/Q}(p) + 1).$$

Here $h(\mathcal{O}_i)$ denotes the number of isomorphism classes of invertible, twosided ideals of $\mathcal{O}_i$. 

117
Proof. See for example [Eic55, Section 4]. □

If \( \mathcal{O} \) is an order in \( \mathbb{Q} \), let \( \mathcal{N}_\mathbb{Q^*}(\mathcal{O}) = \{ x \in \mathbb{Q}^* : x\mathcal{O}x^{-1} = \mathcal{O} \} \) be its normalizer in \( \mathbb{Q}^* \). If \( \mathcal{O} \) is hereditary, [Eic55, Section 4] shows that the number \( h(\mathcal{O}) \) occurring in Eichler’s mass formula is given by

\[
  h(\mathcal{O}) = \frac{2^r \cdot \# \text{Cl}(K)}{|\mathcal{N}_{\mathbb{Q^*}}(\mathcal{O}) : \mathbb{Q^*}\mathcal{O}^*}| = \frac{2^r \cdot \# \text{Cl}(K) \cdot [\mathbb{Q}^* : \mathcal{O}^*]}{|\mathcal{N}_{\mathbb{Q^*}}(\mathcal{O}) : \mathbb{Q^*}|} \tag{7.3.1}
\]

where \( r \) denotes the number of prime ideals dividing \( D(\mathcal{O}) \).

Combining equation (7.3.1) with Eichler’s mass formula yields a major improvement over Corollary 6.3.2.

**Theorem 7.3.4** If \( \mathcal{O} \) is a hereditary order in \( \mathbb{Q} \) with type number \( t \), then

\[
  d^{1/n}_K < \left( \frac{\left( t/2 \right)^{1/n} \cdot 4\pi^2 \cdot (3/2)^{\omega_2(K)/n}}{2^{3/2}} \right)^{2/3}.
\]

Here \( \omega_2(K) \) denotes the number of prime ideals in \( \mathcal{O} \) of norm 2.

Proof. Let \( r \) and \( \{ \mathcal{O}_1, \ldots, \mathcal{O}_t \} \) be as in Theorem 7.3.3. Eichler’s mass formula and equation (7.3.1) show that

\[
  t \geq \frac{1}{|\mathcal{N}_{\mathbb{Q^*}}(\mathcal{O}_i) : \mathbb{Q}^*|} \frac{\mathcal{M}(\mathcal{O})}{2^r \cdot \# \text{Cl}(K)}
\]

\[
  \geq 2^{1-n} \cdot |\zeta_K(-1)| \prod_{p | d_{\mathbb{Q}/K}^{1/2}} \frac{N(p) - 1}{2}
\]

\[
  \geq 2^{1-n} \cdot |\zeta_K(-1)| \cdot 2^{-\omega_2(K)} \geq 2 d^{3/2}_K \cdot \frac{\zeta_K(2)}{(2\pi)^2} \cdot 2^{-\omega_2(K)}
\]

\[
  > \frac{2 d^{3/2}_K}{(2\pi)^2} \cdot \left( 4/3 \right)^{\omega_2(K)} \cdot 2^{-\omega_2(K)} \geq \frac{2 d^{3/2}_K}{(2\pi)^2} \cdot (2/3)^{\omega_2(K)}
\]

as claimed. □

**Corollary 7.3.5** If \( \mathcal{O} \) is a hereditary order in \( \mathbb{Q} \) with type number \( t \leq 2 \), then

\[
  d^{1/n}_K < (4\pi^2 \cdot (3/2)^{\omega_2(K)/n})^{2/3}. \tag{7.3.2}
\]

There are 358 totally real number fields \( K \) that satisfy equation (7.3.2). The largest one has degree 8.

Proof. Let \( K \) be a totally real number field that satisfies equation (7.3.2) and let \( n \) be its degree. Then \( d^{1/n}_K < (6\pi^2)^{2/3} < 15.20 \). The bounds from [BD08] imply that \( n \leq 10 \). If \( n = 10 \), then [BD08] shows that \( d^{1/n}_K < 15.20 \) is only possible if \( \omega_2(K) \leq 1 \). But \( d^{1/n}_K < (4\pi^2 \cdot (3/2)^{1/10})^{2/3} < 11.92 \) is impossible by [Voi08]. The case \( n = 9 \) is ruled out similarly. The tables [Voi08] list all totally real number fields \( K \) with \( d^{1/n}_K \leq 15.5 \) and degree at most 8. The result follows from an explicit search. □

There are 358 totally real number fields \( K \) that satisfy equation (7.3.2). The largest one has degree 8.
With the possible base fields at hand, the enumeration of all ternary quadratic \(\mathfrak o\)-lattices with class number at most 2 can now proceed as in Chapter 6. However, enumerating the quaternion orders of type number 2 directly as it is done in [KL16], is much more efficient:

Suppose a hereditary order \(\mathcal O\) in \(\mathbb Q\) has type number \(t \leq 2\). Let \(D(\mathcal O) = d_{\mathbb Q/K}^{1/2} \cdot \mathfrak l\) for some integral, square-free ideal \(\mathfrak l\) of \(\mathfrak o\). As in the proof of Theorem 7.3.4 it follows that

\[
2 \geq t \geq 2^{1-n} |\zeta_K(-1)| \cdot \prod_{p\mid d_{\mathbb Q/K}^{1/2}} (\text{Nr}_{K/Q}(p) - 1) \cdot \prod_{p\mid \mathfrak l} (\text{Nr}_{K/Q}(p) + 1).
\]

For any field \(K\) from Corollary 7.3.5, there are only finitely many pairs of integral, square-free coprime ideals \((d_{\mathbb Q/K}^{1/2}, \mathfrak l)\) of \(\mathfrak o\) that satisfy this inequality. From \(d_{\mathbb Q/K}\) one obtains the quaternion algebra \(\mathbb Q\) as explained in Remark 3.4.2. Every order \(\mathcal O\) in \(\mathbb Q\) with discriminant \(D(\mathcal O) = d_{\mathbb Q/K}^{1/2} \cdot \mathfrak l\) is hereditary and of the same type. The construction of such an order can be done as follows.

1. Start with a maximal order \(\mathcal O\) in \(\mathbb Q\) which can be computed using Zassenhaus’ Round2 algorithm, see [Zas72].

2. For \(p\mid \mathfrak l\) find an isomorphism \(\varphi_p: \mathcal O/p\mathcal O \to (\mathfrak o/p)^{2\times 2}\). This boils down to find some nonzero element in \(\mathcal O/p\mathcal O\) with reducible minimal polynomial over \(\mathfrak o/p\).

3. For \(p\mid \mathfrak l\) replace \(\mathcal O\) by the preimage of the upper triangular matrices under \(\varphi_p\).

Once \(\mathcal O\) is constructed, a set of representatives of the conjugacy classes of hereditary orders with discriminant \(D(\mathcal O)\) can be obtained from [KV10, Algorithm 7.10]. This yields the type number of \(\mathcal O\). So the enumeration of all definite, hereditary quaternion orders with type number 2 is now clear, see also [KL16, Algorithm 4.5]. The non-hereditary orders with type number at most 2 can be gotten by successively taking preimages under \(\text{Id}_p\) but two questions still remain:

- At which places \(p\) does one have to compute preimages of \(\text{Id}_p\) to reach all Gorenstein orders of type number 2?
- How to compute the type number of such a preimage.

These two questions are answered by the following lemma.

**Lemma 7.3.6** Let \(\Lambda, \mathcal O\) be Gorenstein orders in \(\mathbb Q\) such that \(\text{Id}_p(\Lambda) = \mathcal O\) for some \(p\in \mathcal P(\mathfrak o)\). Let \((\mathcal O_1, \ldots, \mathcal O_t)\) represent the conjugacy classes of all orders in \(\mathbb Q\) which are of the same type as \(\mathcal O\).

1. The normalizer \(N_{\mathcal O^*}(\mathcal O_i)\) acts on

\[
X_i := \{ \Lambda' \subset \mathbb Q; \Lambda' \text{ is of the same type as } \Lambda \text{ and } \text{Id}_p(\Lambda') = \mathcal O_i\}
\]

by conjugation. Let \(\{\Lambda_{i,1}, \ldots, \Lambda_{i,n_i}\}\) represent the orbits of this action. Then

\[
\{\Lambda_{i,j} \mid 1 \leq j \leq n_i, \ 1 \leq i \leq t\}
\]
is a complete set of representatives of the conjugacy classes of all orders in \( \mathcal{Q} \) which are of the same type as \( \Lambda \).

2. Suppose \( p \nmid \mathcal{D}(\mathcal{O}) \) and \( \Lambda_p \) is not hereditary. Then \( \#X_i \geq \text{Nr}_{K/Q}(p)(\text{Nr}_{K/Q}(p) - 1)/2 \). In particular, the type number of \( \Lambda \) is at least

\[
\sum_{i=1}^{t} \left\lceil \frac{\text{Nr}_{K/Q}(p)(\text{Nr}_{K/Q}(p) - 1)}{2 \cdot \#\mathcal{N}_{\mathcal{O}_i}} \right\rceil.
\]

Proof. See [KL16, Lemmata 5.4 and 5.5].

A complete description of the method to compute all definite Gorenstein quaternion orders with a given type number is presented in [KL16, Algorithms 4.5 and 5.6]. If one applies these algorithms to the fields \( K \) given by Corollary 7.3.5, one finally obtains the following result.

**Theorem 7.3.7**

1. There are 4194 types of definite Gorenstein quaternion orders of type number one over 30 different base fields. The largest field has degree 5.

2. There are 18 538 types of definite Gorenstein quaternion orders of type number two over 75 different base fields. The largest field has degree 6.

A complete list of representatives is available electronically from [Kir16].

Note that since the type number of an quaternion order agrees with the type number of its Gorenstein closure, the above result actually classifies all definite quaternion orders with type number at most 2. From that classification it is fairly easy to enumerate all definite quaternion orders which ideal class number (i.e. the number of isomorphism classes of invertible left ideals) at most 2. See [KL16, Section 6] for details.

### 7.4 The general case

As mentioned in the beginning of this chapter, the enumeration of all one-class genera of definite quadratic lattices is due to G. Watson, see also [KL13]. D. Lorch very recently extends this classification to arbitrary totally real number fields in his thesis [Lor].

Applying Algorithm 6.5.4 to the fields \( K \) and ranks \( m \geq 4 \) given by Corollary 6.3.2 yields the following results.

**Theorem 7.4.1** The number of similarity classes of genera of definite quadratic \( \mathbb{Z} \)-lattices with rank \( m \geq 4 \) and class number \( h \leq 2 \) is given by the following table.

<table>
<thead>
<tr>
<th>( m )</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
<th>11</th>
<th>12</th>
<th>13</th>
<th>14</th>
<th>15</th>
<th>16</th>
<th>( \geq 17 )</th>
</tr>
</thead>
<tbody>

</table>

A complete list of representatives is available electronically from [Kir16].
To state the results for $K \neq \mathbb{Q}$, two specific lattices over $\mathbb{Q}(\sqrt{5})$ will be needed. Let $V_1 := \mathbb{Q}(\zeta_5)$ and let $\sigma_1 : \mathbb{Q}(\zeta_5) \to \mathbb{Q}(\zeta_5)$ the field morphism which maps $\zeta_5$ to $\zeta_5^{-1}$. Similarly, let $V_2 := \left(\frac{-1+\sqrt{5}}{2}\right)$ and let $\sigma_2$ be the canonical involution of $V_2$. Any maximal order $M_i$ of $V_i$ equipped with the trace bilinear form

$$\Phi_i : V_i \times V_i \to V_i, \quad (x,y) \mapsto x\sigma_i(y) + y\sigma_i(x)$$

yields an indecomposable, definite binary or quaternary quadratic $\mathbb{Z}[\frac{1+\sqrt{5}}{2}]$-lattice having class number one. Using the notation of [Neb98], the automorphism groups of $M_1$ and $M_2$ are $\pm D_{10}$ and $(\SL_2(5) \circ \SL_2(5)) : 2$. Note that the lattice $M_2$ is similar to the lattice $H_4$ of [Sch94].

Theorem 7.4.2 Suppose $L$ is a definite quadratic lattice over $K \neq \mathbb{Q}$ of rank $m \geq 4$.

1. There are 607 similarity classes of one-class genera of quaternary lattices over 22 different base fields. The largest field has degree 5.

2. There are 1737 similarity classes of two-class genera of quaternary lattices over 32 different base fields. The largest field has degree 6.

3. If $m \geq 5$ and $h(L) = 1$, then $m \leq 6$ and $K = \mathbb{Q}(\sqrt{5})$. Moreover, either $L$ or $L^\#$ is similar to $\langle 1 \rangle \perp M_2$ or $M_1 \perp M_2$.

4. If $m \geq 5$ and $h(L) = 2$, then $K$ is either $\mathbb{Q}(\sqrt{5}), \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{13})$ or the maximal totally real subfield $\mathbb{Q}(\theta_7)$ of the seventh cyclotomic field $\mathbb{Q}(\zeta_7)$. The number of similarity classes of such genera is as follows.

<table>
<thead>
<tr>
<th>$m$</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\mathbb{Q}(\sqrt{5})$</td>
<td>40</td>
<td>11</td>
<td>2</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>$\mathbb{Q}(\sqrt{2})$</td>
<td>10</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$\mathbb{Q}(\sqrt{13})$</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>$\mathbb{Q}(\theta_7)$</td>
<td>4</td>
<td>2</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

A complete list of representatives is available electronically from [Kir16].

The first and third part of the previous theorem are due to D. Lorch, see also [Lor].

7.5 Unimodular lattices with mass at most 1/2

Let $L$ be a unimodular $\mathfrak{o}$-lattice in a definite quadratic space $(V, \Phi)$ over $K$ such that $\text{Mass}(L) \leq 1/2$.

Lemma 7.5.1 Let $K$ be a totally real number field of degree $n$. Suppose $L$ is a unimodular, definite quadratic $\mathfrak{o}$-lattice of rank $m \geq 3$ and mass at most $1/2$. Then

$$d_K^{1/n} \leq \left(2^{-\frac{1}{2} \cdot \gamma_m \cdot c_m}\right)^{\frac{4}{m(m-1)}}$$
where $\gamma_m$ is given by Theorem 4.2.3 and

$$c_m = \begin{cases} 
3/2 & \text{if } m = 3, \\
9/8 & \text{if } m = 4, \\
1 & \text{otherwise}.
\end{cases}$$

In particular, $m \leq 28$ and $m \leq 14$ whenever $K \neq \mathbb{Q}$.

**Proof.** Suppose first $m$ is odd. Then

$$\lambda(L_p) \geq 1$$

unless $m = 3$ and $\text{Nr}_{K/\mathbb{Q}}(p) = 2$, see Section 4.4 for details. Hence Siegel’s mass formula states that

$$1/2 \geq \text{Mass}(L) = \gamma_m^{-n} d_K^{m(m-1)/4} \prod_{i=1}^{(m-1)/2} \zeta_K(2i) \cdot \prod_p \lambda(L_p)$$

$$\geq \gamma_m^{-n} d_K^{m(m-1)/4} \cdot \left\{ \begin{array}{ll}
(2/3)^n & \text{if } m = 3, \\
1 & \text{otherwise}.
\end{array} \right.$$ 

Suppose now that $m$ is even. Let $\text{disc}(L) = d \cdot (K^*)^2$. Then $\lambda(L_p) \geq 1$ unless $p$ ramifies in $K(\sqrt{d})$ or all of the following conditions hold: $m = 4$, $\text{Nr}_{K/\mathbb{Q}}(p) = 2$ and $d \in (K^* p)^2$.

Hence

$$1/2 \geq \text{Mass}(L)$$

$$= \gamma_m^{-n} d_K^{m(m-1)/4} \cdot \text{Nr}_{K/\mathbb{Q}}(d_K(\sqrt{d}/K))^{(m-1)/2} \cdot \prod_{i=1}^{m/2-1} \zeta_K(2i) \cdot \mathcal{L}_K(\chi_d, m/2) \cdot \prod_p \lambda(L_p)$$

$$\geq \gamma_m^{-n} d_K^{m(m-1)/4} \cdot \left\{ (8/9)^n \text{ if } m = 4, \\
1 \text{ otherwise.} \right.$$ 

This yields the claimed bounds on $d_K^{1/n}$. Note that this bound becomes less than 1 (or less than $\sqrt{5}$) if $m \geq 29$ (or $m \geq 15$).

The previous lemma shows that there are only finitely many pairs $(K, m)$ such that $K$ admits unimodular lattices of rank $m$ and mass at most $1/2$. Further, all possible base fields $K$ are listed in the tables [Voi08].

The assumption that $L$ is unimodular, forces $c(V_p, \Phi) = +1$ for all odd prime ideals $p$ of $\mathfrak{o}$. Hence one can easily adopt Algorithms 6.3.4 and 6.4.1 to just enumerate the genera of unimodular $\mathfrak{o}$-lattices with mass at most $1/2$ and rank $m$.

Let $I_m(K)$ denote the lattice $\mathfrak{o}^m$ equipped with the standard bilinear form. The isometry classes of all unimodular $\mathbb{Z}$-lattices are enumerated in J. Conway and N. Sloane in [CS99] up to rank 25. It turns out that gen($I_{26}(\mathbb{Q})$) and gen($I_{27}(\mathbb{Q})$) are the only genera of unimodular lattices with rank $m \geq 26$. However, I was unable to split these two genera into isometry classes using Kneser’s method since the class numbers and ranks of the lattices are simply too large.

For $K \neq \mathbb{Q}$, splitting the genera was not much of a problem. The numbers of isometry classes, genera and base fields $K$ are given by the following table.
In each case, after splitting the genera into isometry classes, the Mass of the genus was compared with Siegel’s mass formula using the local factors given in Section 4.4. They agreed in all cases, which is a good indicator that the results in Section 4.4 are correct.

Finding the pairs \((K, m)\) such that \(I_m(K)\) has class number one, has been studied extensively by various authors. The case \(m \geq 4\) was settled by J. Dzewas and K. Barner [Dze60, Bar68]. In [Pfe71b], H. Pfeuffer gives a list of 6 fields \(K\) such that \(I_3(K)\) has class number one, but he could not prove the completeness of this list. The enumeration of all unimodular lattices with mass at most 1/2 or [KL16] show that Pfeuffer’s list is in fact complete. More precisely, the following result holds.

**Theorem 7.5.2** Let \(K\) be a totally real number field and let \(m \geq 3\) be an integer. Then \(I_m(K)\) has class number one if and only if one of the following conditions holds.

- \(m = 3\) and \(K\) is one of
  \[
  \mathbb{Q}, \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{5}), \mathbb{Q}(\sqrt{17}), \mathbb{Q}(\theta_7), \mathbb{Q}[x]/(x^3 - x^2 - 3x + 1)
  \]
  where \(\mathbb{Q}(\theta_7)\) denotes the maximal totally real subfield of the seventh cyclotomic field \(\mathbb{Q}(\zeta_7)\).

- \(m = 4\) and \(K \in \{\mathbb{Q}, \mathbb{Q}(\sqrt{2}), \mathbb{Q}(\sqrt{5})\}\).

- \(5 \leq m \leq 8\) and \(K = \mathbb{Q}\).
8 Hermitian lattices with class number at most 2

Let $E/K$ be a CM-extension of number fields and let $(V, \Phi)$ be a definite hermitian space over $E$ of rank $m$. The maximal orders of $K$ and $E$ will be denoted by $\mathfrak{o}$ and $\mathcal{O}$ respectively.

In this chapter a complete classification of definite hermitian lattices over $E$ of rank $m \geq 3$ with class number at most 2 will be given.

8.1 The unary case

Suppose $m = 1$. Up to similarity, the space $V = E$ carries only one definite hermitian form, which is its trace bilinear form

$$\Phi: E \times E \to K, \; (x, y) \mapsto \frac{x\overline{y} + y\overline{x}}{2}$$

with the relative norm of $E/K$ as associated quadratic form $Q_\Phi$.

Every $\mathcal{O}$-lattice $L$ in $(E, \Phi)$ is a binary quadratic $\mathfrak{o}$-lattice (but not vice versa). By Lemma 7.2.1, this identification preserves genera and maps isometry classes to proper isometry classes. So the class number of $L$ is given by Theorem 7.2.4. As mentioned in the comment after Theorem 7.2.4, every CM-extension $E/K$ with relative class number one admits unary hermitian lattices with class number one. However, already the list of all such extensions $E/K$ is currently unknown, see [LK06] for an overview of that problem.

8.2 The binary case

In this section, suppose that $m = 2$. If $(V, \Phi)$ admits an $\mathcal{O}$-lattice $L$ of class number at most 2, then Proposition 6.3.6 shows that

$$d_K^{1/n} \leq \left(2^{1/n} \cdot 4\pi^2\right)^{2/(m^2 - 1)} \leq \begin{cases} 14.61 & \text{if } n = 2, \\ 13.53 & \text{if } n \geq 3. \end{cases}$$

A complete list of all such fields $K$ is available from [Voi08].
Let \( \chi \) be the non-trivial character of \( \text{Gal}(E/K) \). Siegel’s mass formula 4.2.7 shows that 
\[
 h(L) \geq \#\mu(E) \cdot \text{Mass}(L) = \#\mu(E) \cdot 2(8\pi^3)^{-n} \cdot d_K^2 \cdot \zeta_K(2) \cdot \prod_{p \in \mathfrak{P}(o)} \lambda(L_p)
\]
\[
 \geq \#\mu(E) \cdot 2(8\pi^3)^{-n} \cdot d_K^2 \cdot \zeta_K(2)
\]
\[
 = (2\pi)^{-n} \cdot \frac{2 \cdot \#\text{Cl}(E)}{Q \cdot \#\text{Cl}(K)} \cdot d_K^{3/2} \cdot \zeta_K(2). \tag{8.2.1}
\]
where \( Q \in \{1, 2\} \) denotes the Hasse unit index of \( E/K \). In particular, the above inequality (which is sharp for some lattices \( L \)) does not involve the relative discriminant \( d_{E/K} \). So for \( m = 2 \), the enumeration of all possible CM-fields \( E/K \) that might occur is a relative class number problem. Even the most recent bounds on relative class numbers do not allow the enumeration of all possible fields \( E \) in practice (although they show that it is indeed a finite problem).

To see how bad the situation is, let \( K = \mathbb{Q}(\sqrt{5}) \). By [Has85, Satz 25], the Hasse unit index of \( E/K \) is always 1. Thus equation 8.2.1 shows that 
\[
 \#\text{Cl}(E) \leq \frac{16\pi^4}{\zeta_K(2) \cdot 5^{3/2}} = 120.
\]
Assuming for a moment that \( E/\mathbb{Q} \) is cyclic, [Lou06, Corollary 20] shows that 
\[
 120 \geq \#\text{Cl}(E) \geq \frac{2}{3} \exp(1) \pi^2 \cdot \frac{\sqrt{d_E/5}}{(\log(d_E/5)/2 + 2 + \gamma - \log(4\pi))^2}
\]
where \( \gamma \) denotes the Euler-Mascheroni constant. Hence \( \sqrt{d_E/5} < 9.163 \cdot 10^5 \) and thus \( d_E < 4.198 \cdot 10^{12} \). So a complete enumeration of all such extensions \( E/K \) is simply impossible. Also note that without the assumption that \( E/\mathbb{Q} \) is cyclic, the bounds on \( d_E \) get much worse, see for example [Lou06, Theorems 28 and 31].

However for \( K = \mathbb{Q} \), the classification of all possible extension \( E/\mathbb{Q} \) is indeed possible. In this case, equation 8.2.1 shows that 
\[
 \#\text{Cl}(E) \leq 4\pi^2/\zeta_\mathbb{Q}(2) = 48.
\]
The imaginary quadratic number fields of class number at most 48 have been enumerated by M. Watkins in his thesis [Wat04]. He shows that \( d_E \leq 462,883 \). An explicit search in Magma shows that there are 10,153 such fields.

If one applies Algorithm 6.5.4 to all these fields \( E \), one obtains the genera of binary definite hermitian forms with class number one or two. Table 8.1 gives the absolute value of the discriminants \( d_E \) as well as the number of similarity classes of genera with class number one or two over \( E \). A complete list is available from [Kir16].
Table 8.1: The imaginary quadratic fields $E$ that admit definite, binary hermitian lattices with class number one or two.

8.3 The general case

Finally suppose that the rank \( m \) of \((V,\Phi)\) is at least 3.

**Definition 8.3.1** Let \( G \) be a genus of \( \mathcal{O} \)-lattices in \((V,\Phi)\) and let \( L \in G \).

1. Suppose \( L_p = \bigoplus_{i=1}^t L_i \) is a Jordan decomposition of \( L \) at some prime ideal \( p \) of \( \mathfrak{o} \).
   Let \( \mathfrak{P} \) be the largest ideal of \( \mathcal{O} \) over \( p \) that is invariant under the involution \( - \).
   Then \( \mathfrak{s}(L_i) = \mathfrak{P}^{s_i} \) for some integers \( s_1 < s_2 < \ldots < s_t \).

   a) If \( p \) is good, the local genus symbol of \( L_p \) is the tuple
   \[
   (s_{1_{\mathfrak{P}}}^{\mathfrak{P}(L_1)}, \ldots, s_{t_{\mathfrak{P}}}^{\mathfrak{P}(L_t)})
   \]
   where the \( i \)-th subscript is determined as follows: If \( \text{disc}(L_i) \in \mathcal{N}(E_p^*) \), then + is written, otherwise − is written.
   Proposition 3.3.5 and Theorem 3.3.6 show that the local genus symbol is well defined and it determines the isomorphism class of \( L_p \) uniquely. For example, \((0^m)\) denotes a unimodular lattice \( L_p \) of rank \( m \) such that \( \text{disc}(L_p) \) is not a local norm (at a place \( p \) that is necessarily ramified in \( E \)). Note that if \( E_p/K_p \) is unramified, then the subtscripts can be recovered from \( \mathfrak{s}(L_i) \) and \( \text{rank}(L_i) \).
   Hence they can be safely omitted at such places.

   b) If \( p \) is bad, then the local genus symbol of \( L_p \) is the tuple
   \[
   (s_{1_{\mathfrak{P}}}^{\text{rank}(L_1)}, \ldots, s_{t_{\mathfrak{P}}}^{\text{rank}(L_t)})
   \]
   where the sign is chosen depending on \( \text{disc}(L_i) \) just as before. Note that in these cases, the local genus symbol is not well defined, i.e. it does depend on the chosen Jordan splitting. However, given any local genus symbol, Corollary 3.3.20 allows the reader to write down an \( \mathcal{O}_p \)-lattice locally isometric to \( L_p \) explicitly. Further, Theorem 3.3.18 can be used to decide whether two local genus symbols define the same isometry class.

In both cases, superscripts being equal to 1 will be omitted.

2. Let \( p_1, \ldots, p_s \) be the prime ideals of \( \mathfrak{o} \) which ramify in \( E \) or at which \( L \) is locally not unimodular. Let \( g_i \) be a local genus symbol of \( L \) at \( p_i \). Then the genus symbol \([g_{1_{p_1}}; \ldots; g_{s_{p_s}}] \) determines \( G \).

Corollary 6.3.7 and Remark 6.3.8 list all possible fields \( E \) and ranks \( m \geq 3 \) such that \( E \) could admit a definite \( \mathcal{O} \)-lattice of rank \( m \) and class number at most 2. Applying Algorithm 6.5.4 to the possible combinations \((E,m)\), yields the following result.

**Theorem 8.3.2** Let \( E/K \) be a CM-extension of number fields. If \( G \) is a genus of definite hermitian lattices over \( E \) of rank \( m \geq 3 \) and class number at most two, then \( m \leq 9 \). A complete list of all such genera is given below and is also electronically available [Kir16].
For any similarity class of genera as in Theorem 8.3.2, the table below lists the following information.

- The rank $m$.
- The extension $E/K$. For any positive integer $r$, let $\zeta_r \in \mathbb{C}$ denote some primitive $r$-th root of unity. So $\mathbb{Q}(\theta_r)$ with $\theta_r := \zeta_r + \zeta_r$ is the maximal totally real subfield of the $r$-th cyclotomic field $\mathbb{Q}(\zeta_r)$.
- A genus symbol of some genus $G$ in the similarity class. Here $p$ denotes a prime ideal of $\mathfrak{o}$ over $p$. This ideal will be unique, except if $p = 11$ and $K = \mathbb{Q}(\sqrt{5})$. In this case the two prime ideals over 11 are labeled $\mathfrak{p}_{11,1}$ and $\mathfrak{p}_{11,2}$.
- The last column lists the factored orders of $\text{Aut}(L)$ where $L$ ranges over a system of representatives of the isometry classes of $G$. Thus this column tells the class number and the mass of $G$.

The similarity classes of genera are grouped by equivalence classes with respect to the equivalence relation from Definition 6.2.3.

9 Quaternionic hermitian lattices with class number at most 2

This chapter gives a complete classification of all definite quaternionic hermitian lattices with class number at most two.

Throughout the chapter, let $E$ be a definite quaternion algebra over some totally real number field $K$ of degree $n$ and $(V, \Phi)$ denotes a definite hermitian space of rank $m$ over $E$. Further, let $\mathfrak{o}$ and $\mathcal{O}$ be maximal orders of $K$ and $E$ respectively.

9.1 Two remarks

The maximal orders in $E$ are not unique. The following remark deals with this nuisance.

**Remark 9.1.1** Let $\mathcal{O}$ and $\mathcal{O}'$ be maximal orders in $E$. There exists some left ideal $\mathfrak{A}$ of $\mathcal{O}$ with right order $\mathcal{O}'$, for example $\mathfrak{A} := \mathcal{O} \mathcal{O}'$. The bijection

$$\{L' \subset E; \text{ } L' \text{ is an } \mathcal{O}'\text{-lattice in } (V, \Phi)\} \rightarrow \{L \subset E; \text{ } L \text{ is an } \mathcal{O}\text{-lattice in } (V, \Phi)\}$$

$$L' \mapsto \mathfrak{A} L'$$

preserves genera, isometry classes and thus class numbers. Note that this map does not necessarily preserve norms and scales. However, if the narrow class group of $K$ is trivial, the situation can be remedied. In that case, $\mathfrak{A} \mathfrak{A} = a^{-1} \mathcal{O}$ for some totally positive scalar $a \in K^*$. Then

$$\{L' \subset E; \text{ } L' \text{ is an } \mathcal{O}'\text{-lattice in } (V, \Phi)\} \rightarrow \{L \subset E; \text{ } L \text{ is an } \mathcal{O}\text{-lattice in } (V, a \Phi)\}$$

$$L' \mapsto (\mathfrak{A} L')^a$$

not only preserves genera, isometry classes and class numbers, but also norms and scales.

So Remark 9.1.1 shows that for the classification of all genera of lattices over $E$ with given class number, it suffices to consider only $\mathcal{O}$-lattices for some maximal order $\mathcal{O}$ of $E$, which will be fixed now once and for all.

The unique decomposition of definite lattices into indecomposable ones is extremely powerful in the case of quaternionic hermitian lattices since there are no obstructions on which hermitian spaces over $E$ exist.

**Remark 9.1.2** Let $G$ be a genus of $\mathcal{O}$-lattices in $(V, \Phi)$.

1. There exists some $\mathcal{O}$-lattice $L_1 \perp \ldots \perp L_s \in G$ such that $L_i$ is indecomposable and $\operatorname{rank}(L_i) \leq 2$. 

141
2. \( h(G) \geq h(\bigcap_{j \in I} L_j) \) for all nonempty subsets \( I \subseteq \{1, \ldots, s\} \).

Proof. 1. Let \( L \in G \) and \( P = \{ \mathfrak{p} \in \mathcal{P}(\mathfrak{o}) : E_{\mathfrak{p}} \) is ramified or \( L_{\mathfrak{p}} \) is not unimodular \}. Given \( \mathfrak{p} \in \mathcal{P}(\mathfrak{o}) \), Algorithm 3.3.2 shows that \( L_{\mathfrak{p}} \cong L_{\mathfrak{p},1} \perp \cdots \perp L_{\mathfrak{p},r} \) with \( \text{rank}(L_{\mathfrak{p},i}) = 2 \) for all \( i < s := \lceil m/2 \rceil \). Since there exists only one hermitian space over \( E_{\mathfrak{p}} \) of a given rank, there exists some definite \( \mathcal{O} \)-lattice \( L_i \) such that \( (L_i)_{\mathfrak{q}} \) is unimodular for all \( \mathfrak{q} \in P \) and \( (L_i)_{\mathfrak{p}} \cong L_{\mathfrak{p},i} \) for all \( \mathfrak{p} \in P \). The result now follows by splitting each lattice \( L_i \) into indecomposable ones, c.f. Theorem 2.4.9.

2. Let \( X = \bigcap_{j \in I} L_j \) and \( Y = \bigcap_{j \notin I} L_j \). Further let \( X_1, \ldots, X_h \) represent the isometry classes of \( \text{gen}(X) \). Then \( X_i \perp Y \in G \) and the unique decomposition of \( \mathcal{O} \)-lattices into irreducible ones shows that \( X_i \perp Y \cong X_j \perp Y \) implies \( X_i \cong X_j \). So \( h(G) \geq h \). \( \square \)

In particular, if the algebra \( E \) admits definite hermitian lattices with class number at most \( B \) and rank \( m \geq 3 \), it must also admit such lattices of rank \( m - 1 \) or \( m - 2 \). This usually rules out a lot of candidates for \( E \).

### 9.2 The unary case

Suppose \( m = 1 \). Up to similarity, \( V = E \) carries only one definite hermitian form, which is its trace bilinear form

\[
\Psi: E \times E \to K, \quad (x, y) \mapsto \frac{x\overline{y} + y\overline{x}}{2}.
\]

The corresponding quadratic form \( Q_{\Psi} \) is the reduced norm \( \text{nr}_{E/K} = N \). Let \( \mathcal{L} \) denote the set of all \( \mathcal{O} \)-lattices in \( (E, \Psi) \), i.e. left ideals of \( \mathcal{O} \). It is well known that the map

\[
\Psi: \mathcal{L} \to \text{Cl}^+(\mathfrak{o}), \quad [\mathfrak{A}] \mapsto [n(\mathfrak{A})]
\]

is surjective, see for example [Rei03, Theorem (35.14)]. The set \( \text{gen}(\mathfrak{A}) \) consists of all \( n(\mathfrak{A})\)-modular \( \mathcal{O} \)-lattices in \( (E, \Psi) \). A system of representatives of the isometry classes in \( \text{gen}(\mathfrak{A}) \) is given by the following theorem.

**Theorem 9.2.1** Let \( \mathfrak{a} \) be an ideal of \( \mathfrak{o} \) and let \( \mathfrak{A}_i, \ldots, \mathfrak{A}_h \) represent the isomorphism classes of the fibre \( \Psi^{-1}(\{[\mathfrak{a}]\}) \). For \( 1 \leq i \leq h \) let \( \Lambda_i := \mathcal{O}_r(\mathfrak{A}_i) \) denote the right order of \( \mathfrak{A}_i \) and let \( \{u_{i,1}, \ldots, u_{i,s_i}\} \) be a system of representatives of \( \mathfrak{o}_{\geq 0}^* / N(\Lambda_i^*) \).

1. There exists \( x_i \in E^* \) such that \( n(\mathfrak{A}_i)x_i\pi_i = \mathfrak{a} \) and there exists \( y_{i,j} \in E^* \) such that \( y_{i,j}\overline{y}_{i,j} = u_{i,j} \).

2. \( (\mathfrak{A}_iy_{i,j}x_i; 1 \leq j \leq r_i, 1 \leq i \leq h) \) represents the isometry classes in the genus of all \( \mathfrak{a} \)-modular lattices in \( (E, \Psi) \). In particular, the class number of this genus is \( \sum_{i=1}^{h} [\mathfrak{o}_{\geq 0}^*: N(\Lambda_i^*)] \).

**Proof.** The first assertion follows from the Norm Theorem of Hasse-Schilling-Maass, see [Rei03, Theorem (33.15)]. For a proof of the second note that the \( \mathcal{O} \)-lattices \( \mathfrak{A}_iy_{i,j}x_i \),
all have rank 1 and they are $\alpha$-modular. Hence they form a single genus. Suppose first that $A_i y_{ij} x_i$ is isometric to $A_k y_{kj} x_k$. Isometries in $(E, \Phi)$ are given by right multiplication with elements of $E$ having norm one. Hence there exists some $x \in E^*$ such that $A_i y_{ij} x_i x = A_k y_{kj} x_k x$ and $xx^* = 1$. Thus $A_i$ is isomorphic to $A_k$ which shows $i = k$ and further $y_{ij} x_i x_i^{-1} y_{ij} x_i^{-1} \in \Lambda_i$. Therefore $N(y_{ij}) N(y_{ij})^{-1} = N(y_{ij} x_i x_i^{-1} y_{ij} x_i^{-1}) \in \mathcal{N}(\Lambda_i)$ implies that $j = \ell$.

Suppose now $\mathfrak{B} \in \text{gen}(\mathfrak{A})$. Then $\mathfrak{B}$ is also $\alpha$-modular, i.e. $n(\mathfrak{B}) = \alpha$. Hence $\mathfrak{B}$ is isomorphic to some $\mathfrak{A}_i$ say $\mathfrak{A}_i x_i = \mathfrak{B}$ with $x \in E^*$. Comparing reduced norms shows that $N(x)$ is a totally positive unit of $\alpha$. Whence $N(x) = N(u) u_{ij}$ for some $1 \leq j \leq r_i$ and some $u \in \Lambda_i^*$. Hence $N(x) = N(u y_{ij})$, say $x = u y_{ij} e$ for some $e \in E^*$ of norm 1. Therefore $x_i^{-1} e x_i$ also has reduced norm 1 and induces an isometry between $\mathfrak{B} = \mathfrak{A}_i x_i = \mathfrak{A}_i y_{ij} e x_i = \mathfrak{A}_i y_{ij} x_i (x_i^{-1} e x_i)$ and $\mathfrak{A}_i y_{ij} x_i$.

The previous algorithm and Remark 9.1.1 immediately show how to decide if $(E, \Phi)$ admits $\mathcal{O}$-lattices with a given class number:

**Algorithm 9.2.2**

**Input:** Some definite quaternion algebra $E$ and some integer $h \geq 1$.

**Output:** True if and only if $E$ admits unary hermitian lattices of class number $h$.

1. Let $\mathcal{O}$ be a maximal order in $E$.
2. Let $\mathfrak{A}_1, \ldots, \mathfrak{A}_\ell$ represent the isomorphism classes of left ideals of $\mathcal{O}$.
3. for $[\alpha] \in \text{Cl}^1(\alpha)$ do
4. \hspace{1em} Let $I = \{1 \leq i \leq \ell : \Psi[\mathfrak{A}_i] = [\alpha]\}$.
5. \hspace{1em} if $\sum_{i \in I} [\alpha^*_i : N(\mathcal{O} \cdot \mathfrak{A}_i^*)] = h$ then return true end if
6. end for
7. return false.

Note that all algorithms for quaternion algebras needed in Algorithm 9.2.2 have been implemented by J. Voight, S. Donnelly and the author in Magma. For example, a maximal order can be computed using the Round2 algorithm of H. Zassenhaus [Zas72] or the more specialized algorithm [Voi13, Algorithm 7.10]. The computation of left ideal class representatives and unit groups is explained in the author’s paper with J. Voight [KV10].

The remainder of this section answers the question which definite quaternion algebras admit hermitian lattices of rank 1 and class number at most 2. By Corollary 6.3.11 such an algebra $E$ over $K$ satisfies

$$d_K^{1/n} \leq 11.6 \quad \text{and} \quad \prod_{p | d_{E/K}} (N_{K/Q}(p) - 1) \leq 2^n \cdot |\zeta_K(-1)|^{-1}.$$ 

This leaves only finitely many candidates, which can easily be worked out using [Voi08] and Remark 3.4.2. Applying Algorithm 9.2.2 to these candidates with $h \in \{1, 2\}$, yields the following result.

**Theorem 9.2.3** There are 69 (148) definite quaternion algebras $E$ over 29 (60) different base fields $K$ that admit unary hermitian lattices of class number one (two).
Tables 9.1 and 9.2 list the degree $n$ of the center $K$, the discriminant $d_K$ as well as $D = \text{Nr}_{K/Q}(d_E/K)^{1/2}$ for these algebras. A complete list is available from [Kir16].

The information given by Tables 9.1 and 9.2 usually does not define the algebra $E$ or even a genus uniquely, but it is certainly enough to recover all genera of class number at most 2 quickly using Magma.

**9.3 The general case**

In this section the rank $m$ of $(V, \Phi)$ over $E$ is assumed to be at least 2.

To be able to write down genera in a unique and efficient way, the following notation will be used.

**Definition 9.3.1** Let $G$ be a genus of $\mathcal{O}$-lattices in $(V, \Phi)$ and let $L \in G$.

1. Suppose $L_p = \bigoplus_{i=1}^{t} L_i$ is a Jordan decomposition of $L$ at some prime ideal $p$ of $\mathcal{O}$. Let $\mathfrak{P}$ be the maximal twosided ideal of $\mathcal{O}$ over $p$. Then $s(L_i) = \mathfrak{P}^{s_i}$ for some integers $s_1 < \ldots < s_t$. The **local genus symbol** of $L_p$ is

$$\left(s_1^{\text{rank}(L_1)}, \ldots, s_t^{\text{rank}(L_t)}\right).$$

Note that the superscripts $\text{rank}(L_i)$ will be omitted whenever they are 1. For example, $(0^m)$ describes a unimodular lattice of rank $m$. By Proposition 3.3.5 and Theorem 3.3.6, the local genus symbol is well defined, i.e. independent from the Jordan decomposition chosen. Moreover, the isomorphism class of $L_p$ is uniquely determined by the local genus symbol.

2. Let $p_1, \ldots, p_s$ be the prime ideals of $\mathfrak{o}$ such that $L_{p_i}$ is not unimodular and let $g_i$ be the local genus symbol of $L$ at $p_i$. Then the genus symbol

$$[g_{p_1}; \ldots; g_{p_s}]$$

is well defined and it uniquely determines the genus $G$. For example, $G$ consists of unimodular lattices if and only if its genus symbol is the empty list $[]$.

Corollary 6.3.11 lists finitely many pairs $(E, m)$ of quaternion algebras $E$ and integers $m \geq 2$ such that $E$ might admit definite hermitian lattices of rank $m$ of class number at most 2. Applying Algorithm 6.5.4 to these candidates, immediately yields the following result.

**Theorem 9.3.2** Let $(V, \Phi)$ be a definite hermitian space over a definite quaternion algebra $E$ of rank $m \geq 2$. Let $\mathcal{O}$ be a maximal order of $E$ and let $G$ be a genus of $\mathcal{O}$-lattices in $(V, \Phi)$. If $h(G) = 1$, then $m \leq 4$ and $h(G) = 2$ implies $m \leq 5$. The complete list of all genera with class number at most 2 is given at the end of this section.

For each similarity class of genera as in Theorem 9.3.2, the table below lists the following information:

- The rank $m$ of the lattices.
- The quaternion algebra $E$. Here $\mathbb{Q}_{\alpha, \infty, p_1, \ldots, p_r}$ denotes the definite quaternion algebra over $K = \mathbb{Q}(\alpha)$ ramified only at the finite places $p_1, \ldots, p_r$. The subscript $\alpha$ will be omitted if $K = \mathbb{Q}$. Further, $\theta_7 = \zeta_7 + \zeta_7^{-1}$ for some primitive 7-th root of unity $\zeta_7 \in \mathbb{C}$.
- The genus symbol of a genus $G$ in the similarity class. Here $p_\beta$ denotes a prime ideal over $\beta$, which will be unique in all cases. The classification shows that the center of $E$ always has narrow class number one. By Remark 9.1.1, this means that the genus symbols are independent from the maximal order $\mathcal{O}$. So there is no need to list $\mathcal{O}$ itself.
- The class number $h(G)$ of the genus.
- The automorphism groups $\text{Aut}(L)$ where $L$ ranges over representatives of the isometry classes in $G$. The naming conventions for the groups are the same as used by G. Nebe in [Neb98] with the exception that the subscripts expressing the quaternion algebras are omitted.
- The factored orders of these automorphism groups.
- Maximal finite subgroups of $\text{GL}_m(E)$ that contain these automorphism groups.

The similarity classes are grouped according to equivalence classes with respect to the equivalence relation from Definition 6.2.3.
\[\begin{array}{cccccc}

Here $S_3 \cong Q_{12}$ is the generalized quaternion group with 12 elements and $G_1 := [\text{SL}_2(3)]_1 \times [\text{SL}_2(3)]_1$. Further, $\theta_7 = \zeta_7 + \bar{\zeta}_7$ where $\zeta_7 \in \mathbb{C}$ denotes some primitive seventh root of unity.
10 Exceptional groups

In the previous chapters, only classical (i.e. orthogonal and hermitian) groups have been studied. This final chapter discusses the problem of enumerating one-class genera of some special subgroups of exceptional algebraic groups. The exposition below is taken from the author’s recent preprint [Kir].

10.1 Preliminaries

In this chapter, let $K$ be a number field of degree $n$ with ring of integers $\mathfrak{O}$. The infinite places of $K$ will be denoted by $\Omega_\infty(K)$. Let $G$ be an absolutely quasi-simple, simply connected algebraic group defined over $K$ such that $\prod_{v \in \Omega_\infty(K)} G(K_v)$ is compact. Then $K$ is totally real. Most of the time, $G$ will be exceptional, i.e. a $K$-form of $G_2, F_4, E_6, E_7, E_8$ or a triality form of $D_4$. By fixing a presentation of $G$, one may assume that $G$ is a subgroup of $GL_m$ for some $m$.

As described in [Bor63, CNP98] any full $\mathfrak{O}$-lattice $L$ in $K^m$ describes an integral group scheme $G$ as follows. For each extension (or completion) $E$ of $K$ with ring of integers $\mathcal{O}$, let $G(\mathcal{O})$ be the stabilizer of $L \otimes \mathcal{O}$ in $G(E)$. Let $A = \{ (\alpha_v)_{v \in \Omega(K)} \mid \alpha_p \notin \mathfrak{O} \text{ for only finitely many } \mathfrak{p} \in \mathfrak{P}(\mathfrak{O}) \}$ be the adele ring of $K$. Suppose $\alpha \in G(A)$. Then $L \cdot \alpha$ denotes the $\mathfrak{O}$-lattice $L'$ with $L' = L' \mathcal{O}_p$ for all $\mathfrak{p} \in \mathfrak{P}(\mathfrak{O})$. Similarly, one defines $G \cdot \alpha$ to be the stabilizer of $L \cdot \alpha$ in $G(K)$. Then $(G \cdot \alpha)(\mathfrak{p}) = \alpha^{-1} G(\mathfrak{p}) \mathcal{O}_p \alpha_p$ for all $\mathfrak{p} \in \mathfrak{P}(\mathfrak{O})$.

Definition 10.1.1 Two integral forms $G$ and $G'$ of $G$ are isomorphic if $G \cdot \alpha = G'$ for some $\alpha \in G(K)$. Similarly, they are said to be in the same genus if $G \cdot \alpha = G'$ for some $\alpha \in G(A)$.

Let $C = \prod_{v \in \Omega_\infty(K)} G(K_v) \times \prod_{\mathfrak{p} \in \mathfrak{P}(\mathfrak{O})} G(\mathfrak{p})$. Note that $\alpha^{-1} G \alpha$ is the stabilizer of $G \cdot \alpha$ in $G(A)$. Thus

$$CaG(K) \mapsto G \cdot \alpha$$

induces a bijection between the double cosets $C \backslash G(A)/G(K)$ and the isomorphism classes in the genus of $G$.

Lemma 10.1.2 ([CNP98, Proposition 3.3]) Let $G$ be an integral group scheme as above. Then $G(\mathfrak{p})$ is a subgroup of finite index in a maximal compact subgroup of $G(K_\mathfrak{p})$ and $G(\mathfrak{p})$ is a hyperspecial maximal compact subgroup at all but finitely many places $\mathfrak{p} \in \mathfrak{P}(\mathfrak{O})$. 

151
The most important integral group schemes $G$ are those for which $G(o_p)$ is a parahoric subgroup $P_p$ of $G(K_p)$ at each prime ideal $p$ of $\mathfrak{o}$. The genus of such a scheme is uniquely determined by the family $P = (P_p)_{p \in \mathcal{P}(\mathfrak{o})}$. By the previous lemma, $P_p$ is hyperspecial almost everywhere. Such a family $P$ is called coherent in [Pra89].

It is well known ([Bor63, Theorem 5.1]) that the genus of integral forms corresponding to $P$ decomposes into finitely many isomorphism classes represented by $G_1, \ldots, G_{h(P)}$ say. Then the rational number 

$$\text{Mass}(P) = \sum_{i=1}^{h(P)} \frac{1}{\#G_i(o)}$$

is called the mass of $P$. Clearly, $h(P) \geq \text{Mass}(P)$ and $h(P) = 1$ implies $\text{Mass}(P)^{-1} \in \mathbb{Z}$.

### 10.2 The mass formula of Prasad

Let $P$ be a coherent family of parahoric subgroups of $G$ and let $G$ be the unique quasi-split inner $K$-form of $G$. If $G$ is of type $^6D_4$, let $F/K$ be a cubic extension contained in the Galois extension of $K$ over which $G$ splits. In all other cases let $F$ be the minimal extension of $K$ over which $G$ splits. If $G$ splits over $K$, let $s(G) = 0$, if $G$ is a triality form of $D_4$, set $s(G) = 7$ and if $G$ is an outer form of $E_6$ let $s(G) = 6$.

Fix a family $\mathcal{P} = (P_p)_{p \in \mathcal{P}(\mathfrak{o})}$ of maximal parahoric subgroups of $G$ such that $P_p$ is hyperspecial (special) if $G$ splits (does not split) over the maximal unramified extension of $K_p$ and $\prod_{v \in \mathcal{V}(\mathfrak{o})} G(K_v) \times \prod_{p \in \mathcal{P}(\mathfrak{o})} P_p$ is an open subgroup of $G(A)$. See [Pra89, Section 1.2] for more details.

Let $\overline{G}_p$ and $\overline{G}_p$ be the groups $G_p \otimes_{\mathfrak{o}_p} \mathfrak{o}_p/p$ and $G_p \otimes_{\mathfrak{o}_p} \mathfrak{o}_p/p$. By [Tit79, Section 3.5], both these groups admit a Levi decomposition over $\mathfrak{o}_p/p$. Hence there exists some maximal connected reductive $\mathfrak{o}_p/p$-subgroups $M_p$ and $\overline{M}_p$ such that $\overline{G}_p = M_p.R_u(\overline{G}_p)$ and $\overline{G}_p = \overline{M}_p.R_u(\overline{G}_p)$. Here $R_u$ denotes the unipotent radical.

Further, let $r$ be the rank of $G$ and $(d_1, \ldots, d_r)$ denote the degrees of $G$. Then the dimension of $G$ can be expressed as $\dim(G) = 2 \sum_{i=1}^{r} d_i - r$.

In his seminal paper [Pra89], Prasad gave the following explicit formula for $\text{Mass}(P)$.

**Theorem 10.2.1 ([Pra89])**

$$\text{Mass}(P) = d_K^{\dim G/2} \cdot \text{Nr}_{K/\mathbb{Q}}(d_{F/K})^{s(G)/2} \cdot \left( \prod_{i=1}^{r} \frac{d_i - 1)!}{(2\pi)^{d_i}} \right)^n \cdot \prod_{p \in \mathcal{P}(\mathfrak{o})} \beta(P_p) \quad (10.2.1)$$

where $\beta(P_p) = \frac{\text{Nr}_{K/\mathbb{Q}}(p)^{\dim M_p + \dim M_p))}{\# M_p(o/p)} > 1$.

For computational purposes, it is usually more convenient to express $\text{Mass}(P)$ in terms of $\text{Mass}(\mathcal{P})$ which is a product of special values of certain $L$-series of $K$. For $p \in \mathcal{P}(\mathfrak{o})$ let

$$\lambda(P_p) := \beta(P_p)^{-1} = \frac{\text{Nr}_{K/\mathbb{Q}}(p)^{\dim M_p + \dim M_p))}{\# M_p(o/p)}$$
Then \( \text{Mass}(P) = \text{Mass}(P) \cdot \prod_{p \in \mathbb{P}(\phi)} \lambda(P_p) \). Moreover, there is the following empirical fact.

**Lemma 10.2.2 ([PY12, 2.5])** The local factors \( \lambda(P_p) \) are integral.

**Proof.** This follows from explicit computations using Bruhat-Tits theory. In most cases however, these computations can be avoided, see [PY12, 2.5] for details. \qed

### 10.3 The exceptional groups

#### 10.3.1 The case \( G_2 \)

Let \( \mathbb{O} \) be the octonion algebra over \( K \) with totally definite norm form and denote by \( \mathbb{O}^0 \) its trace zero subspace. The automorphism group \( \text{Aut}(\mathbb{O}) \) of \( \mathbb{O} \), i.e. the stabilizer of the octonion multiplication in the special orthogonal group of \( \mathbb{O} \) yields an algebraic group of type \( G_2 \) and \( \mathbb{O}^0 \) is an invariant subspace (cf. [SV00, Chapter 2]). Thus it yields an algebraic group \( G < \text{GL}_7 \) of type \( G_2 \). Further, the construction shows that \( G(K_p) \) is of type \( G_2 \) for all prime ideals \( p \) of \( \mathfrak{o} \).

The extended Dynkin diagram of \( G_2 \) is as follows.

![Dynkin Diagram](image)

By [Tit79, 3.5.2], the parahoric subgroups \( P_p \) of \( G(K_p) \) are in one-to-one correspondence with the non-empty subsets of \( \{0, 1, 2\} \). For any non-empty subset \( T \) of \( \{0, 1, 2\} \) let \( P_p^T \) be the parahoric subgroup of \( G(K_p) \) whose Dynkin diagram is obtained from the extended Dynkin diagram of \( G_2 \) by omitting the vertices in \( T \). For example, \( P_p^{\{0\}} \) is hyperspecial and \( P_p^{\{2\}} \) is of type \( A_2 \).

**Theorem 10.3.1** Suppose \( P \) is a coherent family of parahoric subgroups of \( G \) such that \( h(P) = 1 \). Then \( K = \mathbb{Q} \) and \( P_p \) is hyperspecial for all primes \( p \notin \{2, 3, 5\} \). The possible combinations \( (T_2, T_3, T_5) \) such that \( P_p = P_p^{T_p} \) for \( p \in \{2, 3, 5\} \) are given below.

The last column gives the label of the group \( G(\mathbb{Z}) \) in the list of all groups of order \( \text{Mass}(P)^{-1} = \#G(\mathbb{Z}) \) as defined by the small group database ([BEO01]).

\(^1\)The group is isomorphic to a index 2 subgroup of the automorphism group of the root lattice \( \mathbb{F}_4 \).
Proof. If $G$ is of type $G_2$, then $F = K$, $r = 2$ and $(d_1, d_2) = (2, 6)$. In particular, 
$\dim G = 2(d_1 + d_2) - r = 14$. Thus Theorem 10.2.1 shows 
\[ h(P) \geq d_K^7 \left( \frac{15}{32\pi^8} \right)^n. \]
Hence $h(P) = 1$ implies 
\[ d_K^{1/n} \leq \left( \frac{32\pi^8}{15} \right)^{1/7} < 4.123. \]
The tables [Voi08] show that $K$ is one of $\mathbb{Q}$, $\mathbb{Q}(\sqrt{d})$ with $d \in \{2, 3, 5, 13\}$ or the maximal totally real subfield $\mathbb{Q}(\theta_7)$ of the seventh cyclotomic field $\mathbb{Q}(\zeta_7)$. The assumption $h(P) = 1$ forces $\text{Mass}(P)^{-1} \in \mathbb{Z}$. Hence $\text{Mass}(P)^{-1} \in \mathbb{Z}$ by Lemma 10.2.2. The exact values of $\text{Mass}(P) = 2^{-2n}|\zeta_K(-1)\zeta_K(-5)|$ for the various possible base fields $K$ is given in the following table.

<table>
<thead>
<tr>
<th>$K$</th>
<th>$\mathbb{Q}$</th>
<th>$\mathbb{Q}(\sqrt{2})$</th>
<th>$\mathbb{Q}(\sqrt{3})$</th>
<th>$\mathbb{Q}(\sqrt{5})$</th>
<th>$\mathbb{Q}(\sqrt{13})$</th>
<th>$\mathbb{Q}(\zeta_7)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\text{Mass}(P)$</td>
<td>$\frac{1}{3.37.7} = \frac{1}{#G_2(2)}$</td>
<td>361</td>
<td>1681</td>
<td>12096</td>
<td>33463</td>
<td>84672</td>
</tr>
</tbody>
</table>

This shows that $K = \mathbb{Q}$ as claimed. For any given prime $p$, the local factor $\lambda(P_p)$ is given by the following table.

<table>
<thead>
<tr>
<th>root system of $P_p$</th>
<th>$\emptyset$</th>
<th>$A_1$</th>
<th>$A_2$</th>
<th>$A_1 \times A_1$</th>
<th>$G_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\lambda(P_p)$</td>
<td>$p^8 - p^6 - p^2 + 1$</td>
<td>$p^6 - 1$</td>
<td>$p^3 + 1$</td>
<td>$p^3 + p^2 + 1$</td>
<td>$1$</td>
</tr>
</tbody>
</table>

If $p \geq 23$ then $\#G_2(2) \cdot (p^3 + 1) > 1$ and therefore $P_p$ is hyperspecial. For $p < 23$ one can simply check all possible combinations of $P_p$ which yield $\text{Mass}(P)^{-1} \in \mathbb{Z}$. This yields precisely the claimed combinations.

Let $B$ be an Iwahori subgroup of $G$. The set of all $\mathbb{Z}_pB$-invariant lattices in $\mathcal{O}_0^\dagger$ have been worked out in [CNP98]. For each candidate $P$ one finds some lattice $L$ such that the stabilizer $G(\mathbb{Z})$ of $L$ in $G_2 < \text{GL}(\mathcal{O}_0^\dagger)$ is of type $P$. It turns out that $\text{Mass}(P)^{-1} = \#G(\mathbb{Z})$ in all cases. \hfill $\square$

10.3.2 The case $F_4$

**Proposition 10.3.2** Suppose $G$ is of type $F_4$. Then there exists no coherent family $P$ of parahoric subgroups of $G$ with class number one.

**Proof.** If $G$ is of type $F_4$, then $r = 4$ and $(d_1, \ldots, d_4) = (2, 6, 8, 12)$. In particular, $\dim G = 2\sum d_i - r = 52$ and Theorem 10.2.1 shows that 
\[ h(P) \geq d_K^{26} \left( \frac{736745625}{8192\pi^{28}} \right)^n. \]
Hence $h(P) = 1$ implies 
\[ d_K^{1/n} \leq \left( \frac{8192\pi^{28}}{736745625} \right)^{1/26} < 2.213 < \sqrt{5}. \]
10.3 The exceptional groups

Thus $K = \mathbb{Q}$ and

$$\text{Mass}(P) = \frac{736745625}{8192\pi^{28}} \cdot \prod_{i=1}^{4} \zeta_{\mathbb{Q}}(d_i) = \frac{1}{4} \prod_{i=1}^{4} |\zeta_{\mathbb{Q}}(1 - d_i)| = \frac{691}{2^{15}3^{6}5^{2}7^{2}13}.$$ 

In particular, $\text{Mass}(P)^{-1} \notin \mathbb{Z}$. □

Note that if $K = \mathbb{Q}$, then $P$ is the model in the sense of Gross and it actually has class number 2 (see [Gro96, Proposition 5.3]).

10.3.3 Triality of $D_4$

Let $G$ be of type $^3D_4$ or $^6D_4$. The field $F$ is a totally real cubic extension of $K$. The extension is normal (and thus cyclic) if and only if $G$ is of type $^3D_4$.

**Lemma 10.3.3** Suppose $G$ is a $K$-form of $D_4$ and $P$ a parahoric family of $G$ with class number one. Then the base field $K$ is either $\mathbb{Q}$, $\mathbb{Q}(\sqrt{d})$ with $d \in \{2, 3, 5, 13, 17\}$ or the maximal totally real subfield $\mathbb{Q}(\theta_e)$ of $\mathbb{Q}(\zeta_e)$ for $e \in \{7, 9\}$.

**Proof.** If $G$ is any form of $D_4$, then $r = 4$ and $(d_1, \ldots, d_4) = (2, 4, 4, 6)$. Hence $\dim G = 2 \sum_i d_i - r = 28$. Thus Theorem 10.2.1 shows that $h(P) \geq \text{Mass}(P) \geq \left(\frac{135}{2^{11}\pi^{16}}\right)^n$. 

So $h(P) = 1$ implies

$$d_k^{1/n} \leq \left(\frac{2^{11}\pi^{16}}{135}\right)^{1/14} < 4.493.$$ 

The result now follows from the tables of totally real number fields [Voi08]. □

Let $\mathfrak{p} \in \mathbb{P}(o)$ be a prime ideal of norm $q$. By [Tit79, Section 4], the type of $G$ at $\mathfrak{p}$ is (using the notation of [Tit79, Tables 4.2 and 4.3])

\[
\begin{align*}
1D_4 & \quad \text{if } \mathfrak{p} \text{ is completely split in } F, \\
^3D_4 & \quad \text{if } F_\mathfrak{p}/K_\mathfrak{p} \text{ is an unramified cubic field extension}, \\
G_2^1 & \quad \text{if } F_\mathfrak{p}/K_\mathfrak{p} \text{ is a ramified cubic field extension}, \\
^2D_4 & \quad \text{if } F_\mathfrak{p} \cong K_\mathfrak{p} \oplus F'_\mathfrak{p} \text{ for some unramified quadratic extension } F'_\mathfrak{p}/K_\mathfrak{p}, \\
B-C_3 & \quad \text{if } F_\mathfrak{p} \cong K_\mathfrak{p} \oplus F'_\mathfrak{p} \text{ for some ramified quadratic extension } F'_\mathfrak{p}/K_\mathfrak{p}.
\end{align*}
\]

Therefore $\beta(P_\mathfrak{p}) = \left(1 - \frac{1}{q^2}\right) \left(1 - \frac{1}{q^2}\right) \cdot \beta'_\mathfrak{p}$ where $\beta'_\mathfrak{p}$ is given by

\[
\begin{align*}
\left(1 - \frac{1}{q^2}\right)^2 & \quad \text{if } \mathfrak{p} \text{ is completely split in } F, \\
1 + \frac{1}{q^2} + \frac{1}{q^4} & \quad \text{if } F_\mathfrak{p}/K_\mathfrak{p} \text{ is an unramified cubic field extension}, \\
1 & \quad \text{if } F_\mathfrak{p}/K_\mathfrak{p} \text{ is a ramified cubic field extension}, \\
\left(1 + \frac{1}{q^2}\right) \left(1 - \frac{1}{q^2}\right) & \quad \text{if } F_\mathfrak{p} \cong K_\mathfrak{p} \oplus F'_\mathfrak{p} \text{ for some unramified extension } F'_\mathfrak{p}/K_\mathfrak{p}, \\
1 - \frac{1}{q^2} & \quad \text{if } F_\mathfrak{p} = K_\mathfrak{p} \oplus F'_\mathfrak{p} \text{ for some ramified extension } F'_\mathfrak{p}/K_\mathfrak{p}.
\end{align*}
\]
The functional equation for L-series shows that
\[
\text{Mass}(\mathcal{P}) = 2^{-4n} \cdot |\zeta_K(-1) \cdot \mathcal{L}_K(\chi, -3) \cdot \zeta_K(-5)|
\]  
(10.3.1)
where \(\chi\) denotes the non-trivial character of Gal\((F/K)\), see also [PY12, Section 2.8].

**Proposition 10.3.4** If \(G\) is of type \(3D_4\) or \(6D_4\) then there exists no coherent parahoric family of class number one.

**Proof.** If \(G\) admits a one-class parahoric family \(\mathcal{P}\), then
\[
1 \geq \text{Mass}(\mathcal{P}) \geq \text{Mass}(\mathcal{P}) > d_F^{7/2} \cdot d_F^{7/2} \cdot \left(\frac{135}{2^{11} \pi^{16}}\right)^n
\]
or equivalently, \(d_F \leq d_K^{-1} \cdot \left(\frac{2^{11} \pi^{16}}{135}\right)^{2n/7}\). By Lemma 10.3.3, there are only finitely many candidates for \(K\). For each such field \(K\), [Voi08] lists all possible cubic extensions \(F\) that satisfy the previous inequality. It turns out that \(K = \mathbb{Q}\) and \(F = \mathbb{Q}[x]/(f(x))\) where \(f(x)\) is one of the ten polynomials given below. In each case, Mass\((\mathcal{P})\) can be evaluated explicitly using equation (10.3.1).

<table>
<thead>
<tr>
<th>(f(x))</th>
<th>Mass((\mathcal{P}))</th>
</tr>
</thead>
<tbody>
<tr>
<td>(x^3 - x^2 - 2x + 1)</td>
<td>79/84672</td>
</tr>
<tr>
<td>(x^3 - 3x - 1)</td>
<td>199/36288</td>
</tr>
<tr>
<td>(x^3 - x^2 - 3x + 1)</td>
<td>577/12096</td>
</tr>
<tr>
<td>(x^3 - x^2 - 4x - 1)</td>
<td>11227/157248</td>
</tr>
<tr>
<td>(x^3 - 4x - 1)</td>
<td>1333/6048</td>
</tr>
<tr>
<td>(x^3 - x^2 - 4x + 3)</td>
<td>1891/6048</td>
</tr>
<tr>
<td>(x^3 - x^2 - 4x + 2)</td>
<td>2185/3024</td>
</tr>
<tr>
<td>(x^3 - x^2 - 4x + 1)</td>
<td>925/1344</td>
</tr>
<tr>
<td>(x^3 - x^2 - 6x + 7)</td>
<td>4087/4032</td>
</tr>
<tr>
<td>(x^3 - x^2 - 5x - 1)</td>
<td>19613/12096</td>
</tr>
</tbody>
</table>

The result now follows from the fact that Mass\((\mathcal{P})\) is an integral multiple of Mass\((\mathcal{P})\) and therefore never the reciprocal of an integer. \(\Box\)

**10.3.4 The case \(E_6\)**

Let \(G\) be a form of \(E_6\). The assumption that \(GK_v\) is anisotropic for all infinite places \(v\) of \(K\) forces \(G\) to be of type \(2E_6\). Thus the splitting field \(F\) of \(G\) is a totally complex quadratic extension of \(K\).

**Proposition 10.3.5** There exists no coherent family \(P\) of parahoric subgroups of \(G\) with class number one.
10.3 The exceptional groups

Proof. If $G$ is of type $2E_6$, then $r = 6$, $(d_1, \ldots, d_6) = (2, 5, 6, 8, 9, 12)$, $s(G) = 26$ and $\dim G = 78$. Suppose $P$ is a parahoric family of class number one. Then Theorem 10.2.1 implies

$$1 = h(P) \geq \text{Mass}(P) > d_K^{39} \cdot \text{Nr}_{K/Q}(d_{F/K})^{13} \cdot \gamma^n \geq d_K^{39} \cdot \gamma^n$$

where $\gamma := \prod_{i=1}^6 \frac{(d_i - 1)!}{(2\pi)^{d_i}}$ and therefore $d_K^{1/n} < \gamma^{-1/39} < 2.31$. Hence $K$ is either $\mathbb{Q}$ or $\mathbb{Q}(\sqrt{5})$.

If $K = \mathbb{Q}(\sqrt{5})$, then $\text{Nr}_{K/Q}(d_{F/K}) \geq 4$. Hence $h(P) > 5^{39} \cdot 4^{13} \cdot \gamma^2 > 1$. So $K = \mathbb{Q}$ and $1 = h(P) > d_K^{13} \cdot \gamma$ implies that $d_P \leq 12$. Thus $F$ is $\mathbb{Q}(\sqrt{-d})$ for some $d \in \{1, 2, 3, 7, 11\}$.

For any $p \in \mathcal{P}(\mathfrak{o})$, the group $G$ is quasi-split over $K_p$. Moreover, the type of $G$ over $K_p$ is $1E_6$, $2E_6$ or $F_4$ (using the notation of [Tit79, Section 4]) depending on whether $p$ is split, inert or ramified in $F$. Thus $\beta(P_p)^{-1}$ equals

$$(1 - q^{-2})(1 - q^{-6})(1 - q^{-8})(1 - q^{-12}) \cdot \begin{cases} (1 - q^{-5})(1 - q^{-9}) & \text{if } p \text{ is split in } F, \\ (1 + q^{-5})(1 + q^{-9}) & \text{if } p \text{ is inert in } F, \\ 1 & \text{if } p \text{ is ramified in } F, \end{cases}$$

where $q = \text{Nr}_{K/Q}(p)$. Let $\chi$ be the nontrivial character of $\text{Gal}(F/\mathbb{Q})$. The functional equation for $L$-series shows that

$$\text{Mass}(P) = 2^{-6} \cdot |\zeta_6(-1) \cdot L_{\mathbb{Q}}(\chi, -4) \cdot \zeta_2(-5) \cdot \zeta_2(-7) \cdot L_{\mathbb{Q}}(\chi, -8) \cdot \zeta_2(-11)|.$$ 

The values for $\text{Mass}(P)$ for all possible fields $F = \mathbb{Q}(\sqrt{-d})$ are

<table>
<thead>
<tr>
<th>$d$</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>7</th>
<th>11</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mass($P$)</td>
<td>$2^{19407}$</td>
<td>$2^{1097308691}$</td>
<td>$2^{559019}$</td>
<td>$2^{610221}$</td>
<td>$2^{7340406625}$</td>
</tr>
</tbody>
</table>

In particular, there exists no parahoric family $P$ such that $\text{Mass}(P)^{-1} \in \mathbb{Z}$. \qed

10.3.5 The case $E_7$

**Proposition 10.3.6** If $G$ is of type $E_7$ then there exists no coherent family $P$ of parahoric subgroups of $G$ with class number one.

**Proof.** If $G$ is of type $E_7$ then $r = 7$, $(d_1, \ldots, d_7) = (2, 6, 8, 10, 12, 14, 18)$ and $\dim G = 133$. If $h(P) = 1$, then Theorem 10.2.1 implies that

$$d_K^{1/n} < \left( \prod_{i=1}^7 \frac{(2\pi)^{d_i}}{(d_i - 1)!} \right)^{2/133} < 1.547 < \sqrt{5}. $$

Thus $K = \mathbb{Q}$ and then

$$\text{Mass}(P) = 2^{-7} \prod_{i=1}^7 |\zeta_2(1 - d_i)| = \frac{691 \cdot 43867}{2^{24}3^{11}5^{2}7^{3}11^{13}19^{1}}$$

shows that $h(P) > 1$ for all parahoric families $P$. \qed
10.3.6 The case $E_8$

**Proposition 10.3.7** If $G$ is of type $E_8$ and $P$ is a coherent family of parahoric subgroups of $G$ then $h(P) \geq 8435$.

*Proof.* If $G$ is of type $E_8$ then $r = 8$ and $(d_1, \ldots, d_8) = (2, 8, 12, 14, 18, 20, 24, 30)$. Thus Theorem 10.2.1 implies that

$$h(P) \geq \text{Mass}(P) > \prod_{i=1}^{8} \frac{(d_i - 1)!}{(2\pi)^{d_i}} > 8434.$$
