Finding normal subgroups

Max Neunhoffer

University of St Andrews

Birmingham, 26.3.2009

The problem

Problem

Let $1 < N \triangleleft G = \langle g_1, \dots, g_k \rangle$ be a *finite group* and N be a *normal subgroup*.

Produce a non-trivial element of N *as a word in the g_i* with “*high probability*”.

- Assume **no more knowledge** about G or N .
- I shall tell you soon why we want to do this.
- We are looking for a **randomised algorithm**.
- Assume we can generate **uniformly distributed random elements** in G .
- “High probability” means **for the moment** “higher than $1/[G : N]$ ”.

Matrix groups ...

Let \mathbb{F}_q be the field with q elements and

$$\mathrm{GL}_n(\mathbb{F}_q) := \{M \in \mathbb{F}_q^{n \times n} \mid M \text{ invertible}\}$$

Given: $M_1, \dots, M_k \in \mathrm{GL}_n(\mathbb{F}_q)$

Then the M_i generate a group $G \leq \mathrm{GL}_n(\mathbb{F}_q)$.

It is **finite**, we have $|\mathrm{GL}_n(\mathbb{F}_q)| = q^{n(n-1)/2} \prod_{i=1}^n (q^i - 1)$

What do we want to determine about G ?

- The group order $|G|$
- Membership test: Is $M \in \mathrm{GL}_n(\mathbb{F}_q)$ in G ?
- Homomorphisms $\varphi : G \rightarrow H$?
- Kernels of homomorphisms? Is G simple?
- Comparison with known groups
- (Maximal) subgroups?
- ...

Constructive recognition

Problem

Let \mathbb{F}_q be the field with q elements and

$$M_1, \dots, M_k \in \mathrm{GL}_n(\mathbb{F}_q).$$

Find for $G := \langle M_1, \dots, M_k \rangle$:

- The group order $|G|$ and
- an algorithm that, given $M \in \mathrm{GL}_n(\mathbb{F}_q)$,
 - **decides**, whether or not $M \in G$, and,
 - if so, expresses M **as word in the M_i** .
- The **runtime** should be bounded from above by a **polynomial in n , k and $\log q$** .
- A Monte Carlo Algorithm is enough. (**Verification!**)

If this problem is solved, we call

$\langle M_1, \dots, M_k \rangle$ **recognised constructively.**

Applications

Possible problems

What is a reduction?

Let $G := \langle M_1, \dots, M_k \rangle \leq \mathrm{GL}_n(\mathbb{F}_q)$.

A **reduction** is a group homomorphism

$$\begin{aligned} \varphi : G &\rightarrow H \\ M_i &\mapsto P_i \quad \text{for all } i \end{aligned}$$

with the following properties:

- $\varphi(M)$ is **explicitly computable** for all $M \in G$
- φ is **surjective**: $H = \langle P_1, \dots, P_k \rangle$
- H is in some sense “**smaller**”
- or at least “**easier to recognise constructively**”
- e.g. $H \leq S_m$ or $H \leq \mathrm{GL}_{n'}(\mathbb{F}_{q'})$ with $n' \log q' < n \log q$

Recursion: composition trees

We get a tree:

Up arrows: inclusions

Down arrows: homomorphisms

Old idea, substantial improvements are still being made

Reduction in the imprimitive case

One case, in which we want to find a reduction, is:

Situation

Let $G \leq \mathrm{GL}_n(\mathbb{F}_q)$ acting linearly on $V := \mathbb{F}_q^{1 \times n}$, such that V is **irreducible**. Assume there is N with $Z(G) < N \triangleleft G$ such that

$$V|_N = W_1 \oplus W_2 \oplus \cdots \oplus W_k,$$

all W_i are **invariant under N** , and G permutes the W_i transitively. Then there is a **reduction** $\varphi : G \rightarrow S_k$.

We can compute the reduction **once N is found**.

Since we can compute **normal closures**, our initial problem is **exactly**, what we need to do.

Things we can do in matrix groups

We can efficiently:

- store and compare elements
- form products and inverses,
- act on vectors, subspaces and matrices,
- compute element orders
- produce uniformly distributed random elements
- use previously assembled data about groups and representations
- compute normal closures (at least Monte Carlo).

The latter means that for $H < G$, we can compute some elements that generate with high probability the smallest normal subgroup of G containing H .

Blind descent (Babai, Beals)

Let $1 \neq x, y \in G$ and G non-abelian.

Assume **at least one of x, y** is contained in a **non-trivial proper normal subgroup**.

We do **not know** which!

Aim: Produce $1 \neq z \in G$ that is contained in a non-trivial proper normal subgroup.

- 1 Consider $c := [x, y] := x^{-1}y^{-1}xy$,
if $c \neq 1$, we take $z := c$.
- 2 If $c = 1$, the elements x and y commute.
If $x \in Z(G)$, take $z := x$.
- 3 Compute generators $\{y_i\}$ for $Y := \langle y^G \rangle$.
 - If some $c_i := [x, y_i] \neq 1$, then take $z := c_i$ as in 1.
 - Otherwise $g \in C_G(Y)$ but $g \notin Z(G)$, thus $Y \neq G$, we take $z := y$.

What we can do

Blind descent

Involution Jumper

What's that?

Jumping classes

Back to our question

Applications

Possible problems

Algorithm 1 (Babai, Beals)

Initialize $1 \neq x := \text{RANDOMELEMENT}(G)$

Repeat K times:

- 1 $y := \text{RANDOMELEMENT}(G)$
- 2 $o := \text{ORDER}(y)$
- 3 $p :=$ some prime divisor of o
- 4 $y' := y^{o/p}$ has order p
- 5 $x := \text{BLINDDESCENT}(x, y')$

Return x

What is the Involution Jumper?

Input: $G = \langle g_1, \dots, g_k \rangle$ and an involution $x \in G$.

repeat

$y := \text{RANDOMELEMENT}(G)$

$c := x^{-1}y^{-1}xy$ **and** $o := \text{ORDER}(c)$

if o **is even then**

return $c^{o/2}$

else

$z := y \cdot c^{(o-1)/2}$ **and** $o' := \text{ORDER}(z)$

if o' **is even then**

return $z^{o'/2}$

until patience lost

return FAIL

Note: If $xy = yx$ then $c = 1_G$ and $o = 1$ and $z = y$.

But this happens rarely.

What does the Involution Jumper do?

Input: $G = \langle g_1, \dots, g_k \rangle$ and an involution $x \in G$.

- **If it does not fail**, it returns an involution $\tilde{x} \in G$.
- $x\tilde{x} = \tilde{x}x$
- Every involution of $C_G(x)$ occurs **with probability** > 0 .
- Using **product replacement** to produce random elements, this is **a practical method** for
 - permutation groups,
 - matrix groups and
 - projective groups,**if nothing goes wrong.**
- It needs **an involution to start with.**

Jumping between classes

Notation: Let x^G denote the **conjugacy class of x in G** .

Lemma

Let $x, a \in G$ be involutions and $g \in G$. Then

$$\text{Prob}(IJ(x) \in a^G) = \text{Prob}(IJ(x^g) \in a^G).$$

or equivalently

Lemma

Let $x \in G$ be an involution. Then the distribution of $IJ(x)^G$ only depends on x^G and **not on the choice of x in x^G** .

Proof: $f(x, y) :=$

$$\begin{cases} [x, y]^k & \text{if } \text{ORDER}([x, y]) = 2k \\ (y[x, y]^k)' & \text{if } \text{ORDER}([x, y]) = 2k + 1 > 1 \text{ and} \\ & \text{ORDER}([y[x, y]^k]) = 2l \\ y^k & \text{if } xy = yx \text{ and } \text{ORDER}(y) = 2k \end{cases}$$

and we have $f(x^g, y^g) = f(x, y)^g$ whenever f is defined. ✓

A Markov chain \mathcal{M}

The **states** are the **conjugacy classes of involutions** in G .

The **transition** is done as follows: At a class a^G :

- Pick an arbitrary involution $x \in a^G$.
- Compute $\tilde{x} := IJ(x)$ until $\tilde{x} \neq \text{FAIL}$.
- Next state is \tilde{x}^G .

By the lemma, the **distribution** of the class \tilde{x}^G **does not depend on the choice of x** .

Theorem

The above Markov chain \mathcal{M} is irreducible and aperiodic and thus has a stationary distribution in which every state has non-zero probability.

Back to the original question

Problem

Let $1 < N \triangleleft G = \langle g_1, \dots, g_k \rangle$ be a *finite group* and N be a *normal subgroup*.

Produce a non-trivial element of N *as a word in the g_i* with “*high probability*”.

- **If** we find an involution in G to start with
 - **and** N contains at least one involution class,
- the IJ will **eventually jump onto an involution class in N** .

A better try

Algorithm 2

Initialize $1 \neq x := \text{RANDOMELEMENT}(G)$ and
 $z := \text{RANDOMINVOLUTION}(G)$

Repeat K times:

- 1 $y := \text{RANDOMELEMENT}(G)$
- 2 $o := \text{ORDER}(y)$
- 3 For a few prime divisors p of o do:
 - $y' := y^{o/p}$ has order p
 - $x := \text{BLINDDESCENT}(x, y')$
- 4 $z := \text{INVOLUTIONJUMPER}(G, z)$
- 5 $x := \text{BLINDDESCENT}(x, z)$

Return x

Examples

In practice, the IJ works extremely well in many cases:

G	N	# hops*
$S_5 \wr S_{10}$	$S_5^{\times 10}$	1.91
$GL(3, 3) \wr S_6 < GL(18, 3)$	$GL(3, 3)^{\times 6}$	1.17
$Sp(6, 3) \otimes 2.O(7, 3) < GL(48, 3)$	$Sp(6, 3) \otimes 1$	1.83

* average number of IJ hops needed to reach N .

Running Algorithm 2 (with $K = 5$) also works nicely:

G	N	succ.
$S_5 \wr S_{10}$	$S_5^{\times 10}$	100%
$GL(3, 3) \wr S_6 < GL(18, 3)$	$GL(3, 3)^{\times 6}$	100%
$Sp(6, 3) \otimes 2.O(7, 3) < GL(48, 3)$	$Sp(6, 3) \otimes 1$	100%

(here we have done 100 runs)

Applications

Possible problems

Situation

Let $G \leq \mathrm{GL}_n(\mathbb{F}_q)$ acting linearly on $V := \mathbb{F}_q^{1 \times n}$, such that V is **irreducible**. Assume there is N with $Z(G) < N \triangleleft G$ such that

$$V|_N = W_1 \oplus W_2 \oplus \cdots \oplus W_k,$$

all W_i are **invariant under N** , and G permutes the W_i transitively. Then there is a **reduction** $\varphi : G \rightarrow S_k$.

We use Algorithm 2, for the result x , do:

- compute the **normal closure** $M := \langle x^G \rangle$,
- use the **MeatAxe** to check whether $V|_M$ is reducible,
- if $x \in N$, we find a reduction.

Possible problems

The **InvolutionJumper** is in trouble, if at least one of the following happens:

- we **do not easily find an involution** in G (like for example in $SL(2, 2^n)$ for big n),
- the involution classes of N have a **small probability in the limit distribution** (when does this happen?),
- the Markov chain **does not converge quick enough** to its limiting distribution (how quick does it converge?),
- the **Involution Jumper returns FAIL too often** (when does this happen?),
- N has **odd order**.

Fortunately: Centralisers of involutions seem to contain enough involutions.
